RADEM VLF ELECTROMAGNETIC SURVEY KIM CLAIM GROUP

VLF ELECTROMAGNETIC METHOD

The VLF (Very Low Frequency) electromagnetic method utilizes the powerful radio wave produced by U.S. Naval transmitters that operate in the very low frequency radio range from 12 to 25 kilocycles.

The direction of the magnetic component of the field from a VLF station is horizontal and perpendicular to the line between the operator and the transmitting station. The Radem receiver unit is essentially a specially designed transistor radio that is used to measure the direction of the magnetic component of the VLF field. The direction of this field, in particular the dip angle, is distorted by the presence of a conductor within the earth. Thus by measuring the dip angles, the presence of a conductor can be detected and its location determined.

The frequency range of the VLF stations is approximately 10 times higher than the normal frequences used in mineral prospecting. This results in the VLF method being more sensitive to lower conductivity and smaller sized bodies than normal EM equipment. Thus, by the same token, the method is sensitive to conductive overburden and conductive overburden will blanket out underlying conductors. The method will also detect weak conductors such as faults and shear zones and thus can be a valuable aid in geological interpretation.

- 2 -

SURVEY INSTRUMENTS

Receiver: Radem EM Unit, Ser. No. 92, Crone

Geophysics Ltd.

Transmitter: U.S. Naval Station, Seattle, Washington.

18.6 kc.

SURVEY PROCEDURE

Readings were taken at one hundred foot intervals along previously established east-west lines. The transmitter station, located at Seattle, Washington, is in a west-southwest direction from the property located at Kimberley, British Columbia. Readings were obtained by holding the instrument horizontal and rotating to obtain a null on the audio and corresponding low on the relative field strength meter, to establish the direction of the field. The instrument was then brought to the vertical position and the null obtained by rotating in the vertical plane. The dip angle was read when the null position was obtained. As the transmitter station is located in the west-southwest the dip angles were recorded as north or south and are a measure of the perpendicular to the magnetic field from the vertical in degrees of dip.

Dip angles have been plotted on the survey plan adjacent to the survey stations. North dips are plotted on the north side of the line; south dips on the south side of the line.

The survey was started on July 2nd and completed on August 8.

SURVEY RESULTS

The survey has been plotted as degrees of dip on a plan at a scale of one inch to 500 feet.

The dip angles reveal northeast trending conductors by giving a cross-over from south dips on the west to north dips on the east. Northwest trending conductors give cross-overs from north dips on the west to south dips on the east. East-west trending conductors will give north dips on the adjacent line to the south and south dips on the adjacent line to the north. As this is a relatively new method of electromagnetic surveying, new methods of data analysis are presently being evolved. One of these new methods is to be published in the December issue of the Canadian Geophysical Bulletin. Data analysis may be used in comparison of results over areas of known surface geology to assist in geological interpretation over areas covered by overburden.

The survey data indicates the location of man made conductors on the property. On map sheets No. 1 and No. 2 a pipeline extends northeastward from claim 73, across claims 74, 51, 50, 27 and 26, giving good cross-overs on every line. On map sheet No. 1 a powerline trends northwest across claims 101, 104, and 120. On map sheet No. 3 the same powerline trends westward across claims 173, 175, 177, 179, 181 and 183 adjacent to line 230 south. This powerline prohibited readings being taken along line 230 south and produced corresponding north and south dips on the adjacent lines. A branch powerline extends northeast from claim 183 across claims 182, 197, and 196 and gave distinct cross-overs. On claims 119, 103, 104, and 120 on map sheet No. 2 northeast trending weak conductors correspond with the geological structure. On map sheet No. 3 weak cross-overs indicate northeast trending conductors on claims 155 to 163 and claims 134 to 140. These northwest trending conductors

correspond to geological contacts and northeast trending shear zones in the northeast striking Alderidge formations and the parallel Purcell diorite sills.

The survey results do not indicate a natural conductor of strong magnitude or conductivity that could be interpreted to represent a conductive mineral deposit.

LEO D. KIBWAN

September 1969

Leo D. Kirwan

CERTIFICATE

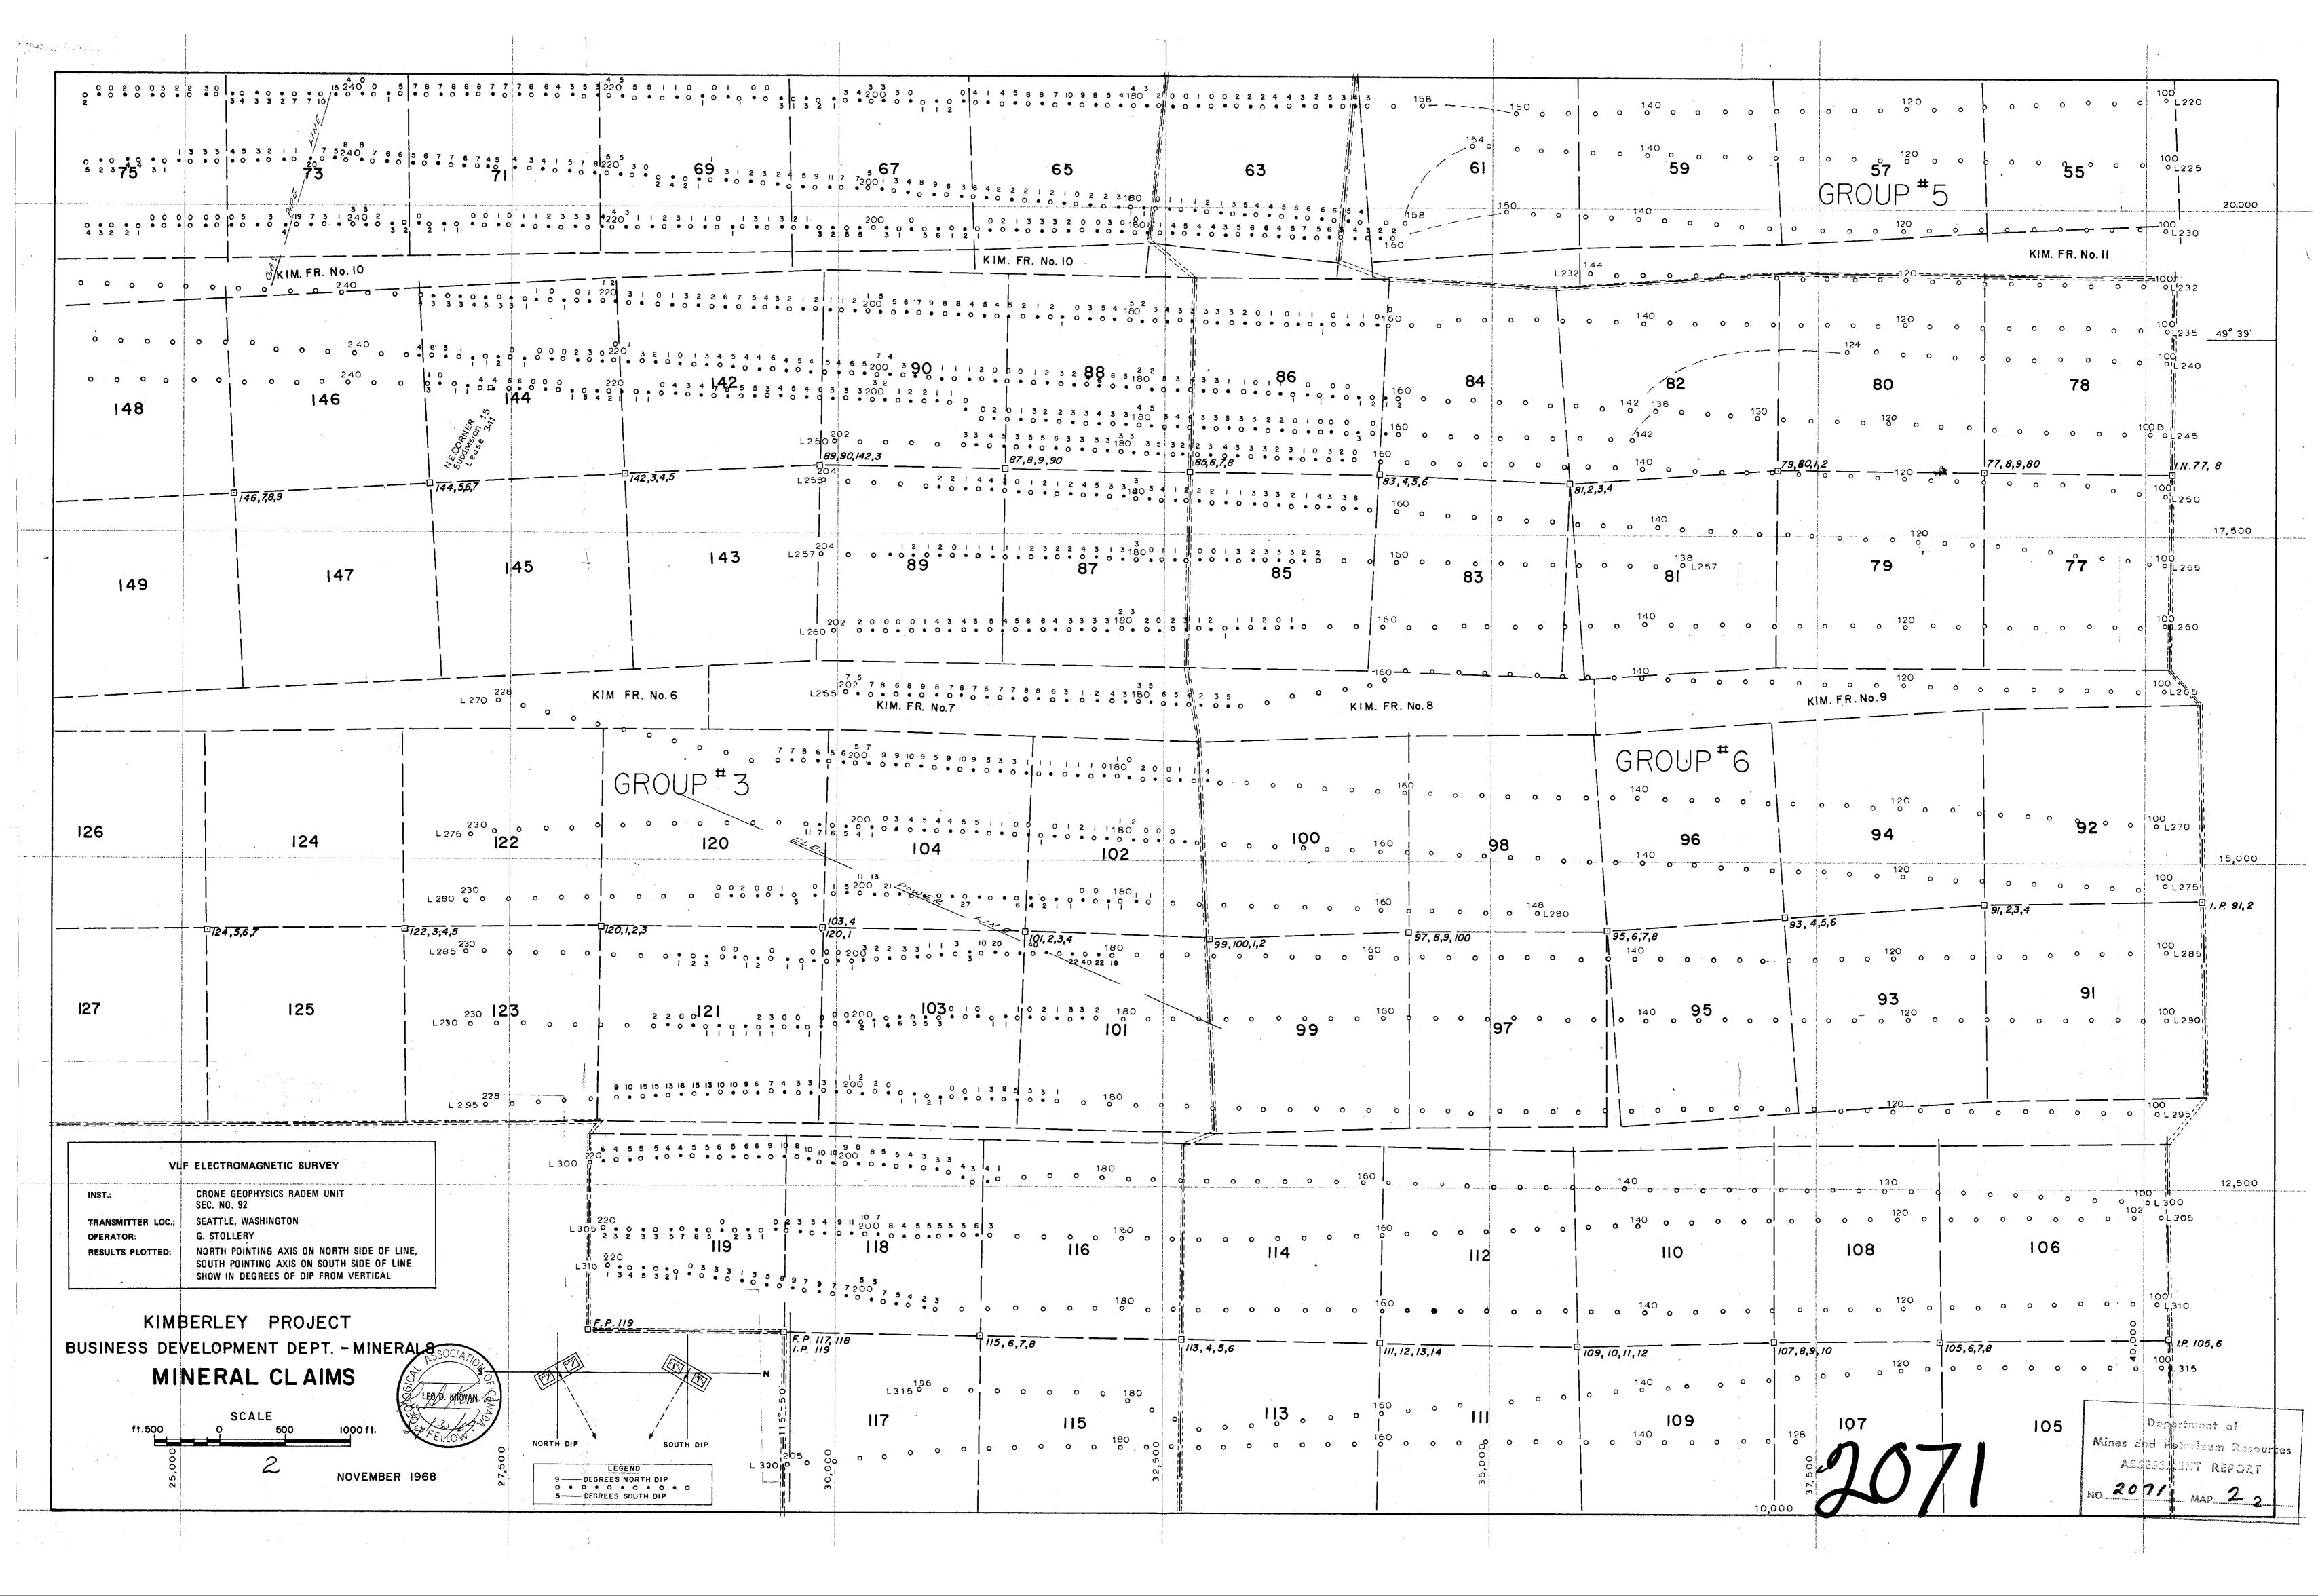

I, Leo D. Kirwan, of the City of Calgary, Province of Alberta, do hereby certify that:

- 1. I am a geologist residing at 5039 Vanstone Crescent, Calgary, Alberta.
- 2. I am a graduate of St. Francis Xavier University with a B.Sc. degree in Geology as of 1952.
- I have worked as a practicing geologist continuously since 1952, and I am now employed in the Minerals Section of Imperial Oil Enterprises Ltd.
- 4. I am a member of the Canadian Mining and Metallurgical Institute and a Fellow of the Geological Association of Canada.

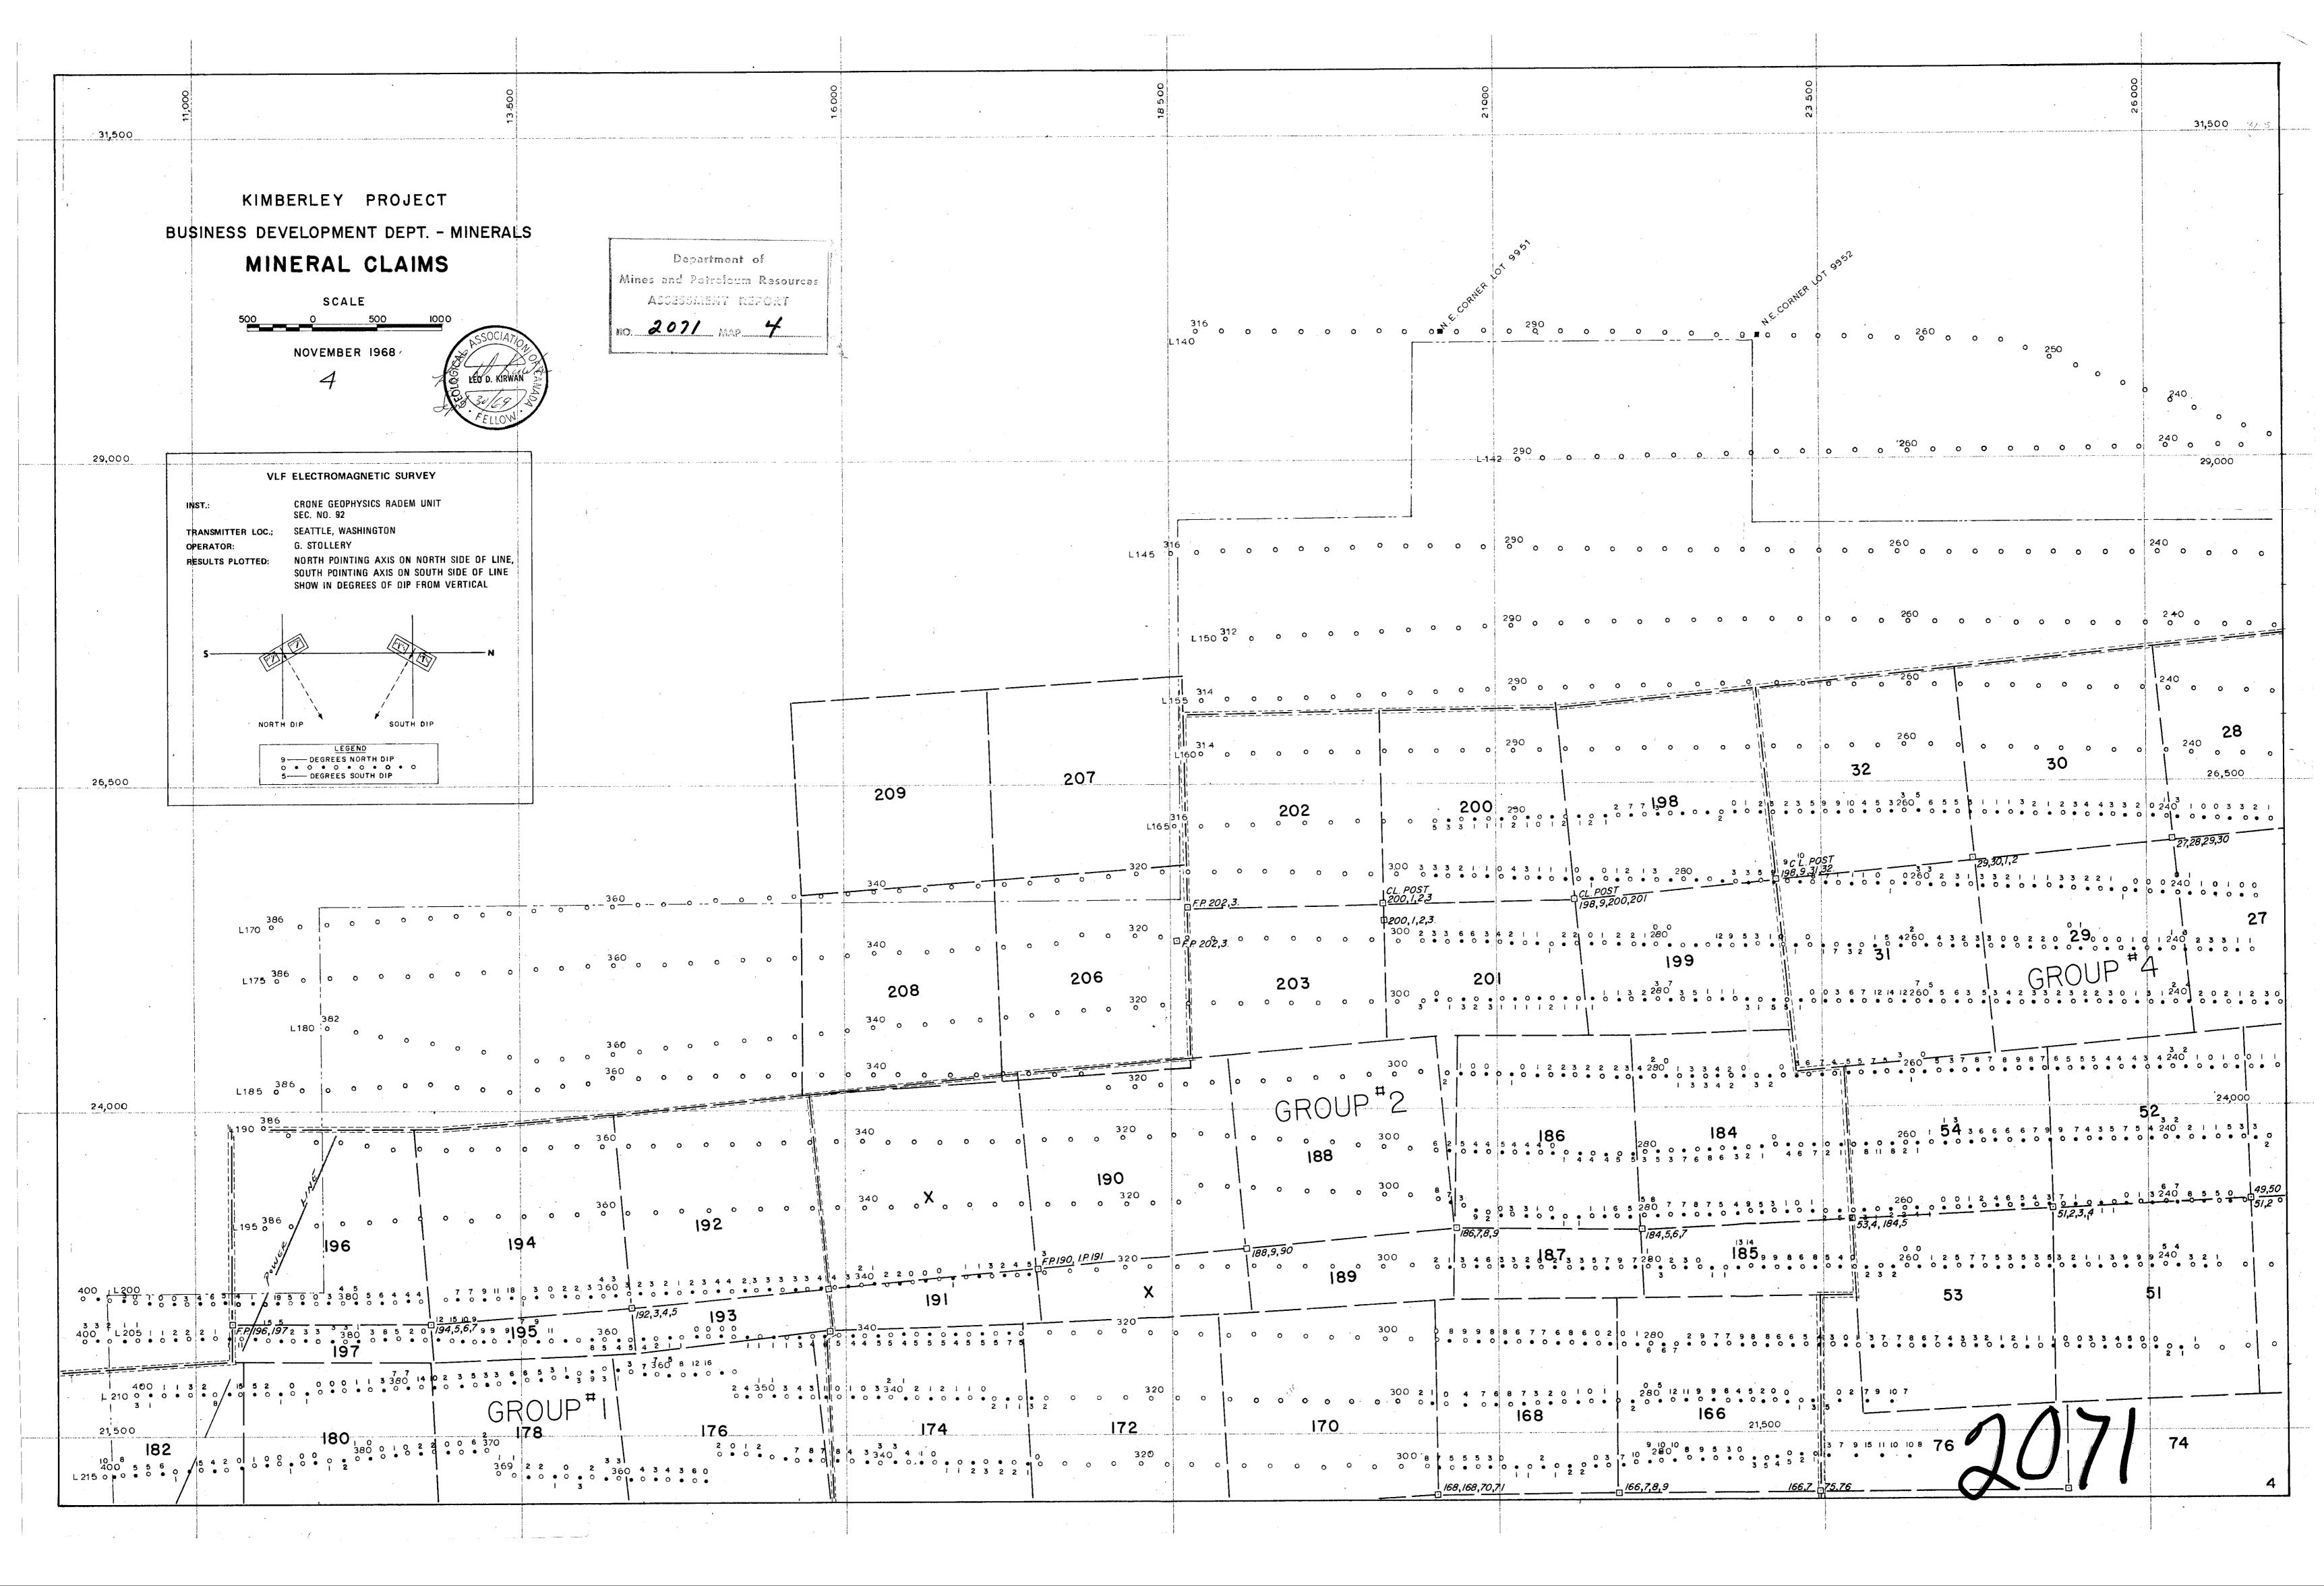

Dated at Calgary

This 30th day of September 1969.

Leo D. Kirwan
