SUMMARY OF EXPLORATION ON HOMESTAKE PROPERTY - KAMAD SILVER CO. LTD.

INTRODUCTION

In August, 1970, Craigmont Mines Limited signed an exploration agreement with Kamad Silver Co. Ltd. (NPL). This agreement covered their one hundred and eleven claim Homestake Property situated approximately two miles west of Squaam Bay, Adams Lake in the Kamloops Mining Division. The property is a former producing barite - silver - lead - zinc prospect.

CONCLUSIONS

- (1) All barite mineralization seen occurs in a crumpled and sheared fissile schist zone.
- (2) Geological mapping suggests that the mineralized zones are lenticular and cut by numerous faults.
- (3) Ground conditions will be poor in underground development immediately adjacent to barite mineralization.
- (4) It is completely impractical to quote probable mining reserves based on the information available at present. Ignoring the obvious geological (structural) complications, any ore reserve calculations based on the present information can at best be classified as possible "geological" reserves.
- (5) It is impractical using surface diamond drilling to further explore along strike the known mineralized zones beyond the 4000 North Co-ordinate.
- (6) Several short surface diamond drill holes in the vicinity of "Barite Bluff" and similar testing from accessible underground workings would greatly enhance any meaningful interpretation of the existing geological information.

RECOMMENDATIONS

- (1) Drill a limited number of short diamond drill holes from the accessible underground workings and from surface immediately north of the Barite Bluff.
- (2) On completion of the drilling program, reinterpret all available geological information with the object of calculating a possible geological ore reserve.

DISCUSSION

General

The prominent rock types occurring on the property are chlorite and quartz - talc - sericite schists of the Adams Lake Series. The existing mine workings are contained in a quartz - talc - sericite schist zone at least 700 feet thick. This zone has a general azimuth of 295° and dips -20° to the north (295°/20°N) and contains all of the barite mineralization seen by the writer. Within the Homestake Creek (Falls Creek) gully, this schist zone is shown to be cut by numerous low angle, easterly dipping thrust faults which have caused considerable crushing and crumpling of the entire zone.

The mineralization in the quartz - talc - sericite schist zone consists of tabular veins and lenticular "ore shoots" of massive barite and sulfides. The sulfides, in approximate order of importance are tetrahedrite, galena, sphalerite, pyrite and chalcopyrite. Grab samples taken from surface and underground vein material suggest that gold is generally present but in quantities less than 0.03 oz./ton.

On completion of a two day general property reconnaissance, detailed work was conducted in two areas, (GE-A-50) namely,

(a) In the immediate vicinity of the old workings. (Stadia survey and 1" = 40' scale geological mapping program.)

(b) Between the west access road and No.2 showing. (Establishment of a grid and approximately five line miles of composite soil samples.)

Survey Control

Using the survey of McWilliams - Whyte - Goble and Associates, British Columbia Land Surveyors of Kamloops, B.C. as a check, a stadia survey was conducted on the area west of Homestake Creek. All known mineralized outcrops adjacent to the old workings were covered by this survey. A 1" = 40' scale contour map (GE-E-42) and a geological overlay plan (GE-D-32) were drawn showing the spacial relationships between old workings, surface diamond drill holes and mineralized outcrops. The contour map and accompanying sections (GE-A-44, GE-A-45, GE-A-46) emphasize the ruggedness of the local terrain.

Geological Mapping

Within the mine area an attempt was made to distinguish between the various facies present in the quartz - talc - sericite schist zone. Unfortunately there is little marked megascopic variation within this zone. However, at least three vague gradational facies appear to be associated with the mineralization, namely:

- (a) Sericite schist (brown) - finely fissile to platy - partly chloritic.
- (b) Talc - Sericite schist - fine grained fissile - very talcose - yellow weathering.
- (c) Talc - Sericite schist (quartzose) - contains nodules of siliceous material, possibly squeezed pebbles - broken surface has grey mottled appearance.

Surface mapping suggests that talc - sericite schist (c) is the rock type most frequently found immediately adjacent to barite mineralization. However, in the underground workings, massive barite was seen bounded by sericite schist (a).

The Barite Bluff is the largest surface exposure of mineralization known to exist on the property. It is a north striking lens of massive barite grading 85% barite, 0.25% copper, 0.65% lead, and 3.20% zinc. Its surface cross-sectional area is approximately 2400 sq. feet (GE-A-45). Surface diamond drill hole Kamad No.1, collared 70 feet north of the bluff, intersected little mineralization (GE-A-44).

Attitudes of drag folds in the vicinity of the Barite Bluff and of a number of small quartz lenses seen throughout the schist zone average 15° in azimuth and - 20° North in plunge.

Numerous faults occur within the schist zone making any current attempt to correlate mineralization in existing surface diamond drill holes unrealistic.

In the accessible underground workings three definite barite - fault contacts having an apparent displacement in excess of six feet were noted. The 1936 B.C. Minister of Mines Annual Report mentions that fault blocks with horizontal movements of up to 40 feet had been encountered in the mine workings.

The best mineralization seen underground occurs 170 feet from the portal. However, the bulk of this ore appears to have been mined out above the level and the western edge of the stope terminates along a fault. Detailed mapping in this area is impossible because of poor ground conditions.

The results of underground chip sampling have been tabulated on plan GE-A-48.

Three grab samples, two from surface and one from underground were selected for Semiquantitative Spectrographic analysis (Table I). No unforeseen mineralogical complications were noted.

Diamond Drilling

To date, no diamond drilling has been conducted by Craigmont Mines Limited. The 9,828 feet of surface drill core stored at the property represents 21 holes previously drilled by Kamad Silver Co. Ltd. This core was relogged to become familiar with rock types, check widths of mineralization and to record apparent banding (schistosity). As in the case of surface mapping, little obvious megascopic variations were noted in rock type.

No record could be found of the co-ordinates for drill holes Kamad Nos. 7, 8 & 9. Their approximate locations were described by Mr. Fred Shukin as follows:

- (a) Kamad No.7 - on west road between survey stations 3714 & 3715.
- (b) Kamad No.8 - below Kamad No.2 and south of survey station 3719.
- (c) Kamad No.9 - on switchback above old millsite near survey station 3746.

Minor packrat rearrangement of stored drill core has taken place, however sufficient footage blocks remained in most boxes to adequately locate areas of interest.

The sample interval used by Kamad's core splitter appears to have been consistently two feet. Unfortunately this interval does not always agree with the widths of mineralization recorded by Mr. F.P. Hodgson. To date we have been unable to reconcile this apparent discrepancy.

Geochemistry: Soil Sampling (GE-C-33-1 to GE-C-33-6)

A 3,800 foot by 800 foot grid was established over the schist zone to the west of the west access road. (GE-A-50) The sample interval was fifty feet along lines 200 feet apart. Each sample analyzed was a composite of several samples taken over the sample interval and the results were plotted at the center of the interval. If soil conditions permitted, each composite represented at least four separate samples taken within the 50 foot interval.

The samples were assayed for copper, zinc, cadmium, lead, silver, molybdenum and barium. Histograms for each metal were drawn and arithmetic mean calculated. (GE-A-51A to 51F, GE-B-19)

Barium was the only metal that did not exhibit well developed anomalous patterns. Without exception the other metals displayed a number of small yet clearly defined anomalous zones, usually coincident. However, after an examination of the fieldnotes, it was concluded that most of the anomalies resulted from highly variable soil conditions. Only two zones warrant further work, namely 4450N - 7400E and 4450N - 9400E.

CERTIFICATE OF QUALIFICATIONS to accompany report entitled, "Craigmont Mines Limited, Project 18-131 Summary of Exploration on Homestake Property - Kamad Silver Co. Ltd. - 29 January, 1971".

I, James F. Bristow, residing at 2125 Parker Drive in Merritt, B.C., certify that:-

I graduated from the University of British Columbia in 1957, receiving the degree B.A. in Geology and Physics.

I have worked continuously in the Mining Industry since graduation.

I have been employed as Chief Geologist at Craigmont Mines Limited, Merritt, B.C. since 2 June, 1965.

Respectfully submitted,

CRAIGMONT MINES LIMITED,

James F. Bristow
J.F. Bristow,
Chief Geologist.
