MAGNETOMETER SURVEY

BARB and RAM CLAIMS

CARIBOO M.D.

B.C.

INTRODUCTION

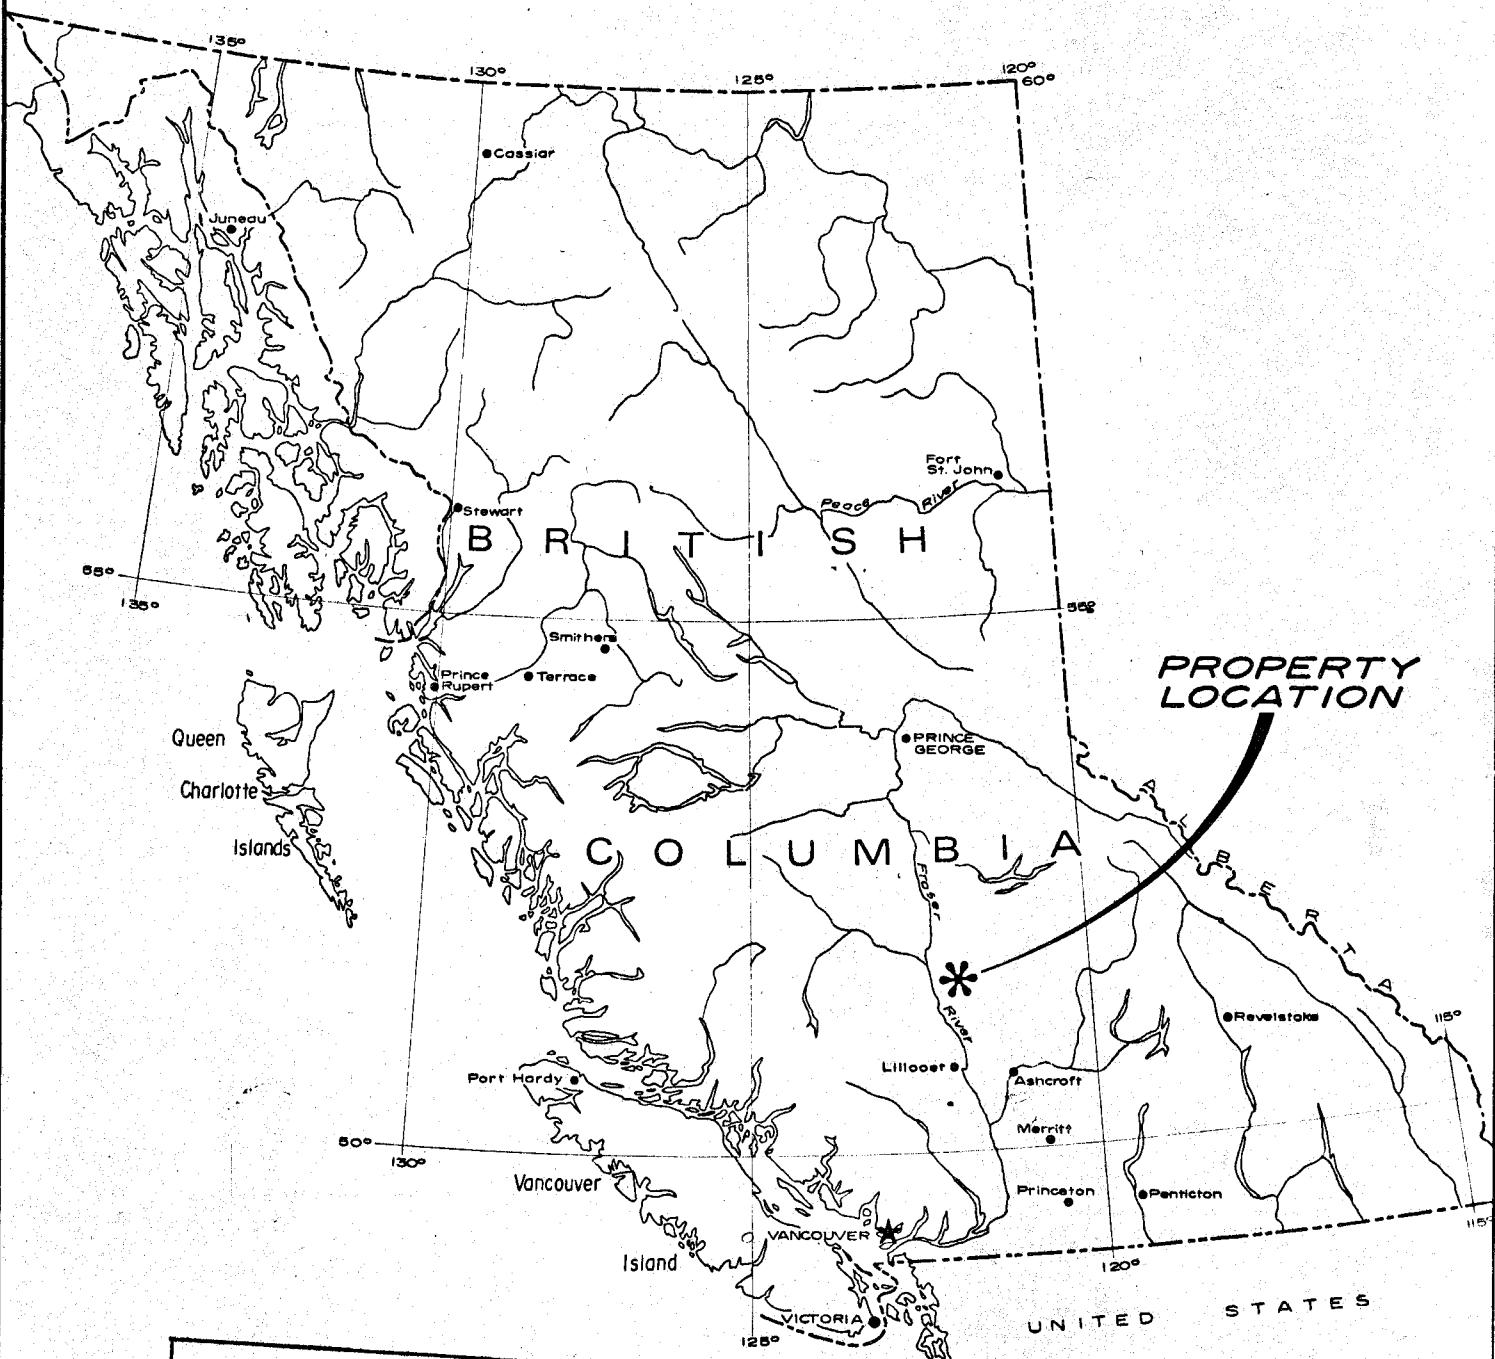

A magnetometer survey was conducted over the Barb 1-12 and Ram 1-8, 10, 12 and 14 claims, September 21-30, 1971.

North-south lines at 400 foot intervals were tied to an east-west base line, and stations were established by cedar stakes every 100 feet along all lines.

Readings taken with a Scintrex G 110 magnetometer were observed and recorded at each station.

The purpose of the survey was to detect any variations in the vertical component of the magnetic field over the surveyed grid on the property.

The object of mapping the magnetic field variations were twofold. Firstly, to locate the contact between the Cache Creek formation and the Granite Mountain intrusive rocks, and secondly, to outline either high or low anomalous areas, either of which might assist in the search for copper sulphide deposits.

LOCATION MAP

SCALE 1"=136 Mls.

Drawn by ALTAIR.	Date Oct. 1971	Allen Geological Engineering Ltd.
Checked by AA	Org. no. M-1	

LOCATION AND ACCESSIBILITY

The property is located in south central British Columbia at approximately $122^{\circ} - 17'$ west longitude and $52^{\circ} - 23'$ north latitude.

This is known as the McLeese Lake Area, and it lies about midway between Williams Lake and Quesnel.

The property is one mile east of McLeese Lake, via secondary roads.

PROPERTY

The area surveyed includes the following adjoining located mineral claims:

Barb 1-12 inclusive

Ram 1-8 inclusive and 10, 12, and 14

The posts and lines have been inspected by the writer and are staked in accordance with the requirements of the British Columbia Mineral Act.

TOPOGRAPHY

The property lies east of McLeese Lake in a benched upland area. The lake is close to 2,800 feet above sea level, and the top of the highest hill on the property is over 3,400 feet elevation.

The general drainage is controlled by Sheridan creek which flows westerly into McLeese Lake a short distance to the north of the property.

GEOLOGY

The McLeese Lake area is underlain by a thick assemblage of highly folded and faulted sedimentary and volcanic rocks of Permian or earlier age, known as the Cache Creek group.

The Cache Creek group was invaded by granitic rocks of Jurassic or early Cretaceous age. A large exposure of these is included on the northern part of the Gibbex property and it extends northerly through the Gibraltar property and Granite Mountain.

Overlying the older granitic, sedimentary and volcanic rocks are Tertiary volcanics made up of vesicular basalt, andesite and minor tuffaceous rocks. These occur as thin remnants over some areas, but form an extensive cover west of the McLeese and Cuisson drainage areas.

The largest mineralized zones encountered to date in the McLeese Lake area occur in the altered granitic rocks of the Granite Mountain batholith. Along with pyrite, chalcopyrite, bornite and molybdenite there is lesser pyrrhotite, hematite, and copper carbonates and oxides. The granitic rocks have been foliated, kaolinized and the more common secondary minerals are sericite, talc, chlorite, epidote, calcite and vuggy quartz.

Trenching on the Barb claims has exposed weak pyrite-chalcopyrite mineralization in the granitic rocks, the contact rocks and the Cache Creek sedimentary and volcanic strata.

The contact appears to be nearly flat at this location. There is a wide irregular band of highly silicified Cache Creek material adjacent to granodiorite, quartz diorite, granite, with aplitic and pegmatitic dykes.

MAGNETOMETER SURVEY

A base line was established by chain and Brunton compass across the central portion of the claims area. From this, every 400 feet, north-south lines were surveyed by chain and compass the length of the property. Stations were established each 100 feet with marked cedar stakes. The lines were flagged and blazed.

At each grid station the vertical intensity of the magnetic field was measured in gammas with a Scintrex G 110 fluxgate magnetometer. Diurnal checks were made at least twice daily, and the corrected readings for all stations transferred from a field notebook to an office book and map.

For brevity and simplicity, the magnetometer results are shown on the map as follows:

55680 is shown as 80

55640 is shown as 64

The only reading above 55999 was 56070 and this is shown 607, with the two readings on each side being shown as 583 and 581.

The northern two-thirds of the property, which is underlain by granitic rocks and the contact zone with the Cache Creek series, show little or no variation from 55,640 to 55,670 gammas.

The southerly claims, which are underlain by Cache Creek rocks contain several zones of slightly higher magnetic intensity.

SURVEY RESULTS

The entire area underlain by intrusive and contact rocks is lacking in magnetic variance. The vertical component of the magnetic field over this area is 55,660 gammas with only minor areas showing as low as 55600 to 55620 range.

On the Barb 1-4 and Ram 1-6, there are three weak anomalous zones, as follows:

Anomaly #1

A large U-shaped anomaly peaks on the boundary between the Barb 2 and 3 claims at 56070 gammas. An irregular surrounding area lies within the 55810-55900 range. A second elongated zone in this range extends from the Ram 1 across the southwest corner of the Ram 2 and extends south-easterly close to the Barb 1 claim.

These are surrounded by a large area in the 55,710-55800 gamma range.

6.

There are no outcrops on Anomaly #1, and it is not known why the field shows this slightly higher range. However, within the Cache Creek group elsewhere, altered volcanic rocks are known to contain disseminated magnetite, and it is possible that this is the reason for the anomaly.

Anomaly #2 and #3

On the Ram 5 there is a 1500-foot zone which is within the 55710-55800 gamma range.

Similarly, on the east side of the Ram 4 and 6 there is a 700-foot anomaly in the 55710-55800 gamma range.

These are just south of the projected contact between the Cache Creek and granitic intrusives and they may be the result of contact metamorphic zones containing minor magnetite or pyrrhotite mineralization.

All three anomalies are only slightly higher than normal and cannot be designated as prime exploration targets.

SUMMARY AND CONCLUSIONS

The magnetometer survey conducted over a 400 by 100 foot surveyed grid on the Barb 1-12 and RAM 1-8, 10, 12 and 14 claims shows that there are no magnetite or pyrrhotite mineral deposits of sufficient size or concentration on the property to be detectable by the technique and instrument used.

It is concluded, therefore, as follows:

- (a) There are no significant areas within the igneous rocks on the northern part of the property which by virtue of magnetic "lows" might be possible porphyry copper deposits such as the Highland Valley deposits.
- (b) There are no significant areas within either the igneous rock, the contact zone or the Cache Creek group which by virtue of magnetic "highs" might be possible copper-iron deposits such as the Craigmont deposit near Merritt.

RECOMMENDATIONS

Whereas the magnetometer results do not provide data which may be useful in the exploration of the property, the lack of such information does not preclude the possibility that copper-molybdenum mineralization such as that on the Gibraltar may be present.

Additional investigations by other techniques will be adviseable before a complete assessment of the potential of the property can be finalized, and such are recommended.

Respectfully submitted,
ALLEN GEOLOGICAL ENGINEERING LTD.
