## SUMMARY

During the period May 16 to June 12, 1973 ten line miles of magnetic surveying and six line miles of I.P. surveying were completed on the Peach Lake Property.

A linear north-west trending magnetic anomaly and several discontinuous highs appear on the isomagnetic map. Several extensive induced polarization anomalies, which are interpreted to reflect 1-2% by volume sulphides were obtained on lines 800 feet apart. The area in which the induced polarization anomaly occurs has been interpreted geologically to be a pyrite zone.

Testing within and peripheral to this zone is warranted because of its location in an interesting geological setting.

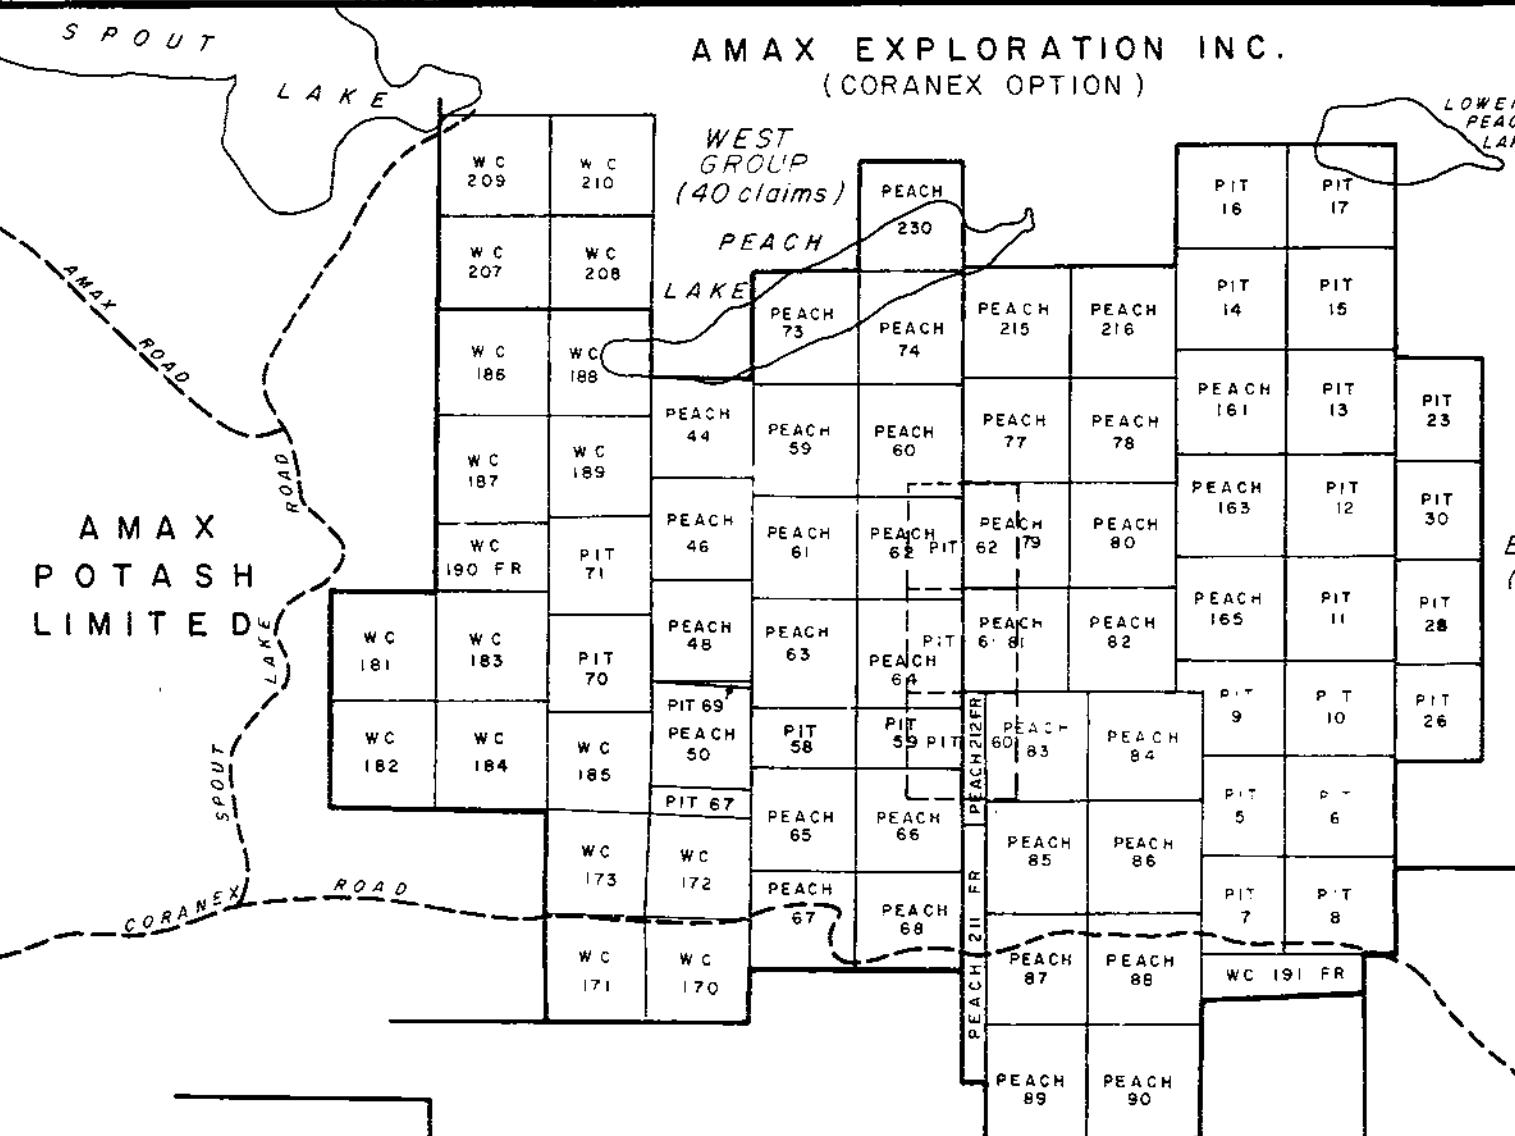

## INTRODUCTION

The Peach Lake Copper Property is located within the Interior Plateau of south-central British Columbia near Lac La Hache. Copper showings discovered in the area by Coranex in 1966 were subsequently staked and explored to 1968. Amax Exploration, Inc. optioned the property in 1972. The following report describes instrumentation, field procedure and results obtained from two geophysical surveys conducted on the West Claim group and two lines that were surveyed on the East Claim group.

### Location and Access

The property is situated approximately 13 air miles north-northwest of Lac La Hache (see Figures 1 and 2). It lies on the south side of Peach Lake between Lower Peach Lake in the east and Spout Lake on the west. Access is via secondary gravel roads north from Lac La Hache and east from Rail Lake.

## LOCATION MAP

### Grid Control

A major grid system was established during 1966-1968 by Coranex Ltd. Several lines were added and some existing lines were refurbished on the northwest portion of the Coranex Grid. In particular lines 56+00E, 28+00E, 16+00W, 24+00W, and 32+00W of the existing grid were recut by powersaw and picketed. Lines 56+00W, 48+00W and 40+00W are new lines which were cut and picketed and lines 52+00W, 44+00W, 28+00W and 20+00W are also new lines which were flagged and chained. All the grid lines surveyed are oriented north-south.

The I.P. survey was executed on the lines which had been cut by powersaw and picketed while the magnetic survey also included taking measurements on the "fill-in" flagged lines.

### GENERAL GEOLOGY

The Peach Lake Property is regionally situated within a northwest to northsouth trending belt up to ten miles wide of Upper Triassic Nicola Group volcanic and sedimentary rocks located near the western limit of the Quesnel Trough. The belt lies between the Jurassic Takomkane batholith on the east and overlying Miocene plateau basalts to the west. Nicola rocks are locally intruded by related diorite to monzonite and locally syenite stocks and dykes. Several such intrusive bodies with associated copper showings are present within the Peach Lake Property.

### MAGNETOMETER SURVEY

#### Introduction and Theory

A ground magnetometer survey was initiated to locate any near surface concentrations of magnetite and also in an effort to aid in the interpretation of major structural trends and lithological contacts.

The magnetism of all rocks is controlled by their content of ferromagnetic material, i.e. substances possessing a relatively high susceptibility and capable of acquiring permanent magnetization. Often skarn mineral assemblages include considerable amounts of the mineral magnetite. High intensity magnetic anomalies may therefore be used as an indicator of skarn environments.

#### Instrument and Procedure

The instrument employed was the Model G-816 Portable Proton Magnetometer, manufactured by Geometrics of 914 Industrial Avenue, Palo Alto, California. This proton free precession magnetometer operates on the principles of nuclear magnetic resonance to produce a measurement of the total magnetic intensity of the earth's field. The instrument is comprised of a console with 12 size "D" flashlight batteries (2.5 kg.), sensor and signal cable (1.8 kg.) and an aluminum staff (0.9 kg.). For this survey the sensor was carried in the back pack rather than on the staff. Values are obtained from a digital display readout and operating temperatures are from -40°C to 85°C.

Coordinates 56+00W and 38+00N were selected as a central base station for the survey. The magnetic intensity at this point was measured at the start and finish of each day. Other base station tie in points were established at 32+00W, 15+00N and 28+00E, 8+00N. On "quiet" days of magnetic variation ( $\pm$  20 gammas) the diurnal variation correction was made as a linear interpolation of time between base station tie in values. During one survey day, June 10, 1973 a large variation was noted in tie in values. A magnetogram for June 10, obtained from the Victoria Magnetic Observatory revealed the presence of a small magnetic storm. The diurnal corrections for this day were interpolated from the magnetogram record.

Measurements were obtained every one hundred feet

along each survey line and corrected values plotted on a scale of  $1''=400$  feet are presented in Figure 3.

#### Results and Discussions

In the western portion of the survey area the data was contoured employing a 1000 gamma contour interval. The data for the two eastern lines, L58+00E and L28+00E is presented in profile format with a vertical scale of one inch = 2000 gammas. The resulting magnetic patterns are displayed in Figure 3.

A continuous anomaly greater than 2000 gammas above background occurs in the northwestern portion of the map area. This anomaly trends west-northwest and is near an interpreted intrusive volcanic contact. Further investigation of this anomaly is warranted because of the occurrence of copper skarn mineralization in this environment. The other spot magnetic highs that appear are due to near surface magnetite concentrations. The lowest magnetic values on the map occur along the profile plot of Line 28+00E within the interval of 14+00S to 23+00S. This is a portion of a conspicuous aeromagnetic low visible on aeromagnetic map sheet 92 P 14.

#### INDUCED POLARIZATION SURVEY

##### Introduction and Theory

During the period June 7 to June 10, 1973 six line miles of induced polarization/resistivity surveying were completed over the property. The survey was initiated to confirm the presence of a northwest trending pyrite zone interpreted from geological mapping. A 200 foot dipole-dipole array was employed and measurements were taken to five separations ( $n=5$ ). The survey was executed by Dennis F. Morrison, an independent geophysical contractor residing in Gravenhurst, Ontario.

The term induced polarization means electrical polarization (i.e. separation of charges) induced by an applied electric field. The cause of this polarization is changes in the mobilities of ions within a rock. At the interfaces between zones of different mobilities, excesses or deficiencies of ions occur. The concentration gradients developed oppose the current flow and cause a polarizing effect. When mineral grains block the pore passages of rocks and a current is applied, a concentration of ions builds up at the electrolyte (water)-metal interface while awaiting an electrochemical reaction which must occur before the electric charge can be transferred from an ion in the electrolyte to a free electron in the metal. The forces which oppose the current flow are said to polarize the interface and the added voltage necessary to drive the current across this barrier is known as "overvoltage".

It takes a finite time to build up overvoltages and one finds that the impedances of these zones (Warburg Impedance) decreases with increasing frequency. In the frequency domain system that was employed, the decrease in the Warburg Impedance was measured between current applied at 0.3 hertz (AC 1) to current applied at 5.0 hertz (AC 2).

Resistivity information is useful in inferring overburden depths, defining abrupt lithological changes, and assessing the importance of any I.P. effects obtained.

#### Instrument and Procedure

A multiple frequency McPhar Induced Polarization system Model P660, was employed in measuring the polarization and resistivity parameters. The transmitter is a manually variable voltage source. The output current can be selected from both polarities and varies from direct current to automatically alternating output frequencies of 0.05, 0.1, 0.3, 1.25, 2.5, and 5.0 hertz.

On this survey the low and high frequencies employed were 0.3 and 5.0 hertz. Power was obtained from a  $2\frac{1}{2}$  KW - 400 hertz motor generator. The maximum output current for the transmitting system is 5 amp. while the maximum output voltage is 690 volts.

The receiver employed was the new 1969 A.C. P660 model. This is a potentiometer type where the amplified and filtered signal is compared with a reference voltage. It is powered by six 8V alkaline transistor batteries and draws 7.5 ma. Total weight including carrying case and batteries is 5 pounds.

Survey procedure required the preparation of a set-up position near the center of each line. The transmitter and its motor generator power supply remained stationary at the set-up position and wires in increasing two hundred foot intervals were strung out in both directions. Care was taken to ensure that the wires were well separated to prevent inductive coupling effects. The ends of the wires were connected to aluminum foil electrodes which had been prepared earlier. The receiving dipole consisting of the receiver and a 200 foot "read" wire also utilized the aluminum foil electrodes where possible. However, once the receiving dipole moved past the last foil emplaced for the transmitting set-up, ground connections were made via porous pots containing a solution of copper sulphate. Radio contact between the receiver and transmitter operations coordinated power "on" and "off" periods.

#### Results and Discussion

The data is presented in eight pseudosections in Appendix II. A plan view displaying anomalous per cent frequency effect values is presented in Figure 4.

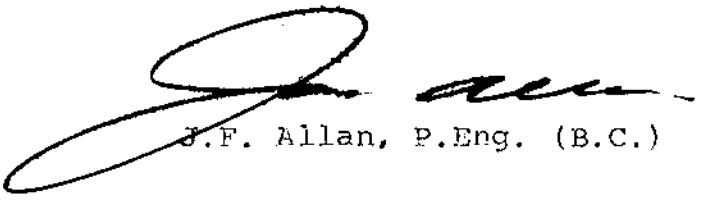

As shown in the plan view the polarizable zone remains open to the south along Lines 48+00W, 40+00W and 32+00W. This

zone is interpreted to contain between 1-3% by volume sulphides.  
No anomalous values were obtained on the two eastern lines,  
28+00E and 58+00E.

The cause of the anomaly is mainly attributed to the presence of pyrite mineralization noted in geological mapping.
