SUMMARY

The NICK Claims 1 - 8 and 21 - 26 were mapped geologically, soil sampled and ground magnetically surveyed from October 5th - 15th, 1973. The resulting information is presented in this report. Slide Mountain group rocks are volcanic and intruded by gabbro. Small amounts of sulfide have been found but copper and nickel values are very low. Copper and nickel soil geochemistry show low and erratic values, interpreted as essentially due to erratic glacial distribution. The ground magnetic map is one of low, erratic magnetic relief. No extension of the mapped rocks is discernable. There is little evidence to indicate economic mineralization is present.

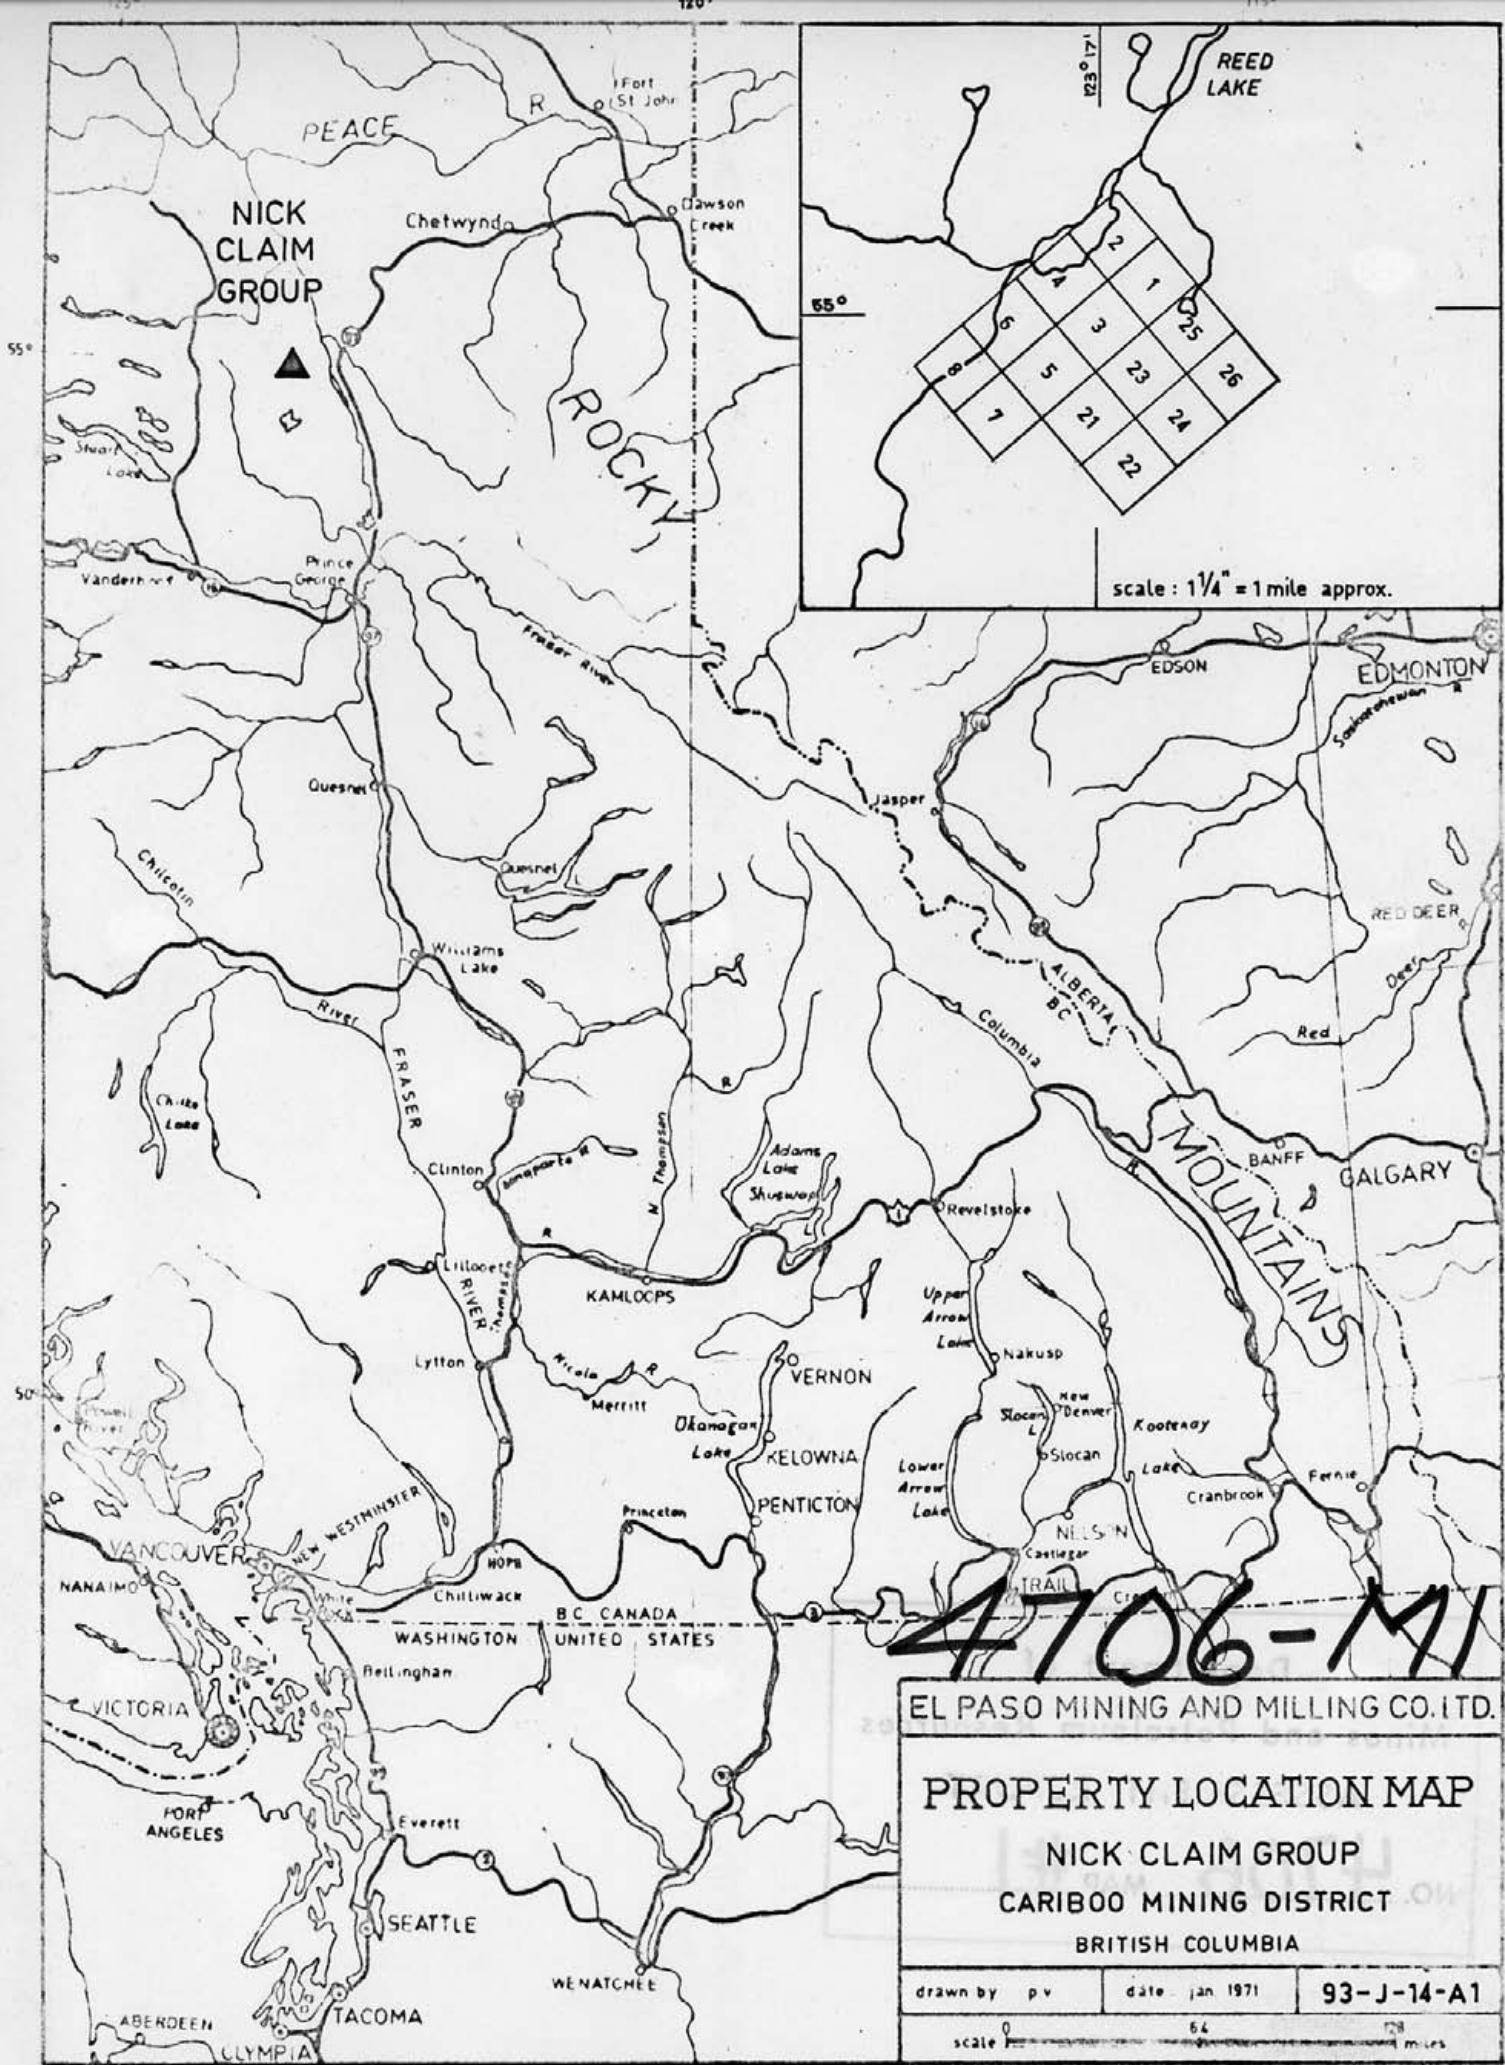

INTRODUCTION

The NICK Claims 1 - 26 were staked by Kol Lovang on October 4th and recorded October 18th, 1972. Because of premature staking, only claims 1 - 8 and 21 - 26 are in good standing. The claimed area had been staked by C. Erickson and M. Warren in 1968 and subsequently allowed to drop.

A gold prospect several miles lower on Reed Creek, at its confluence with McDougall River and a molybdenum prospect on the N-W shores of Reed Lake, witness that the area has mineral potential. Ultrabasic float in the vicinity containing nickel bearing pyrrhotite and chalcopyrite provide additional evidence of mineralization.

LOCATION AND ACCESS

The claims are centered at 55° 00' N 123° 17' W (See Figure 1.) this is just south of Reed Lake. The settlement of McLeod Lake on the Hart Highway lies ten miles to the east. Iso Mines, which explored the molybdenum showing, improved and extended a trail from McLeod to Reed Lake in 1969. This road passes just to the south of the claim group. It is, however, in poor condition and considered impassible for even four-wheel drive vehicles.

TOPOGRAPHY

The claims lie on the Nechako Plateau, just west of the Rocky Mountain Trench. It is on the north-eastern edge of a large area of glacially deposited material. North to north-east moving ice has produced drumlins over much of the surrounding country. In the claim area, the ground is hummocky - a collection of kames, knobs and kettles, as well as drumlins. Vertical relief is in the order of 100 feet. Lowest and highest elevations are 3100 feet at lake level, to a high of 3350 feet. The area is well treed with small to medium sized spruce, balsam, fir and lodgepole pine. Numerous small swamps have copious amounts of alder. The beavers have altered the course of small streams and even have diverted Reed Lake water to flow southward.

SURVEY PROCEDURE

On October 5th, M. Moret, B. Nixon and M. Clemenza set up camp on Lower Reed Lake. From October 6th until they moved out on October 15th, they were occupied in marking grid lines and taking soil samples and magnetometer readings. The writer arrived on October 12th to pick-up the geology and left at the same time as the others.

Procedure was as follows; a baseline striking $N50^{\circ}E$ was flagged from the initial post of NICK 1 - 4. The baseline was numbered 100E and the post numbered 100N. Stations were flagged every 200 feet, south to 54N and north to 114N. Cross lines were run $S40^{\circ}E$ for 3000 feet and then the parallel return line was marked 200 feet further north. Both ends of all lines

were tied to adjoining lines. Lines were run by Silva Compass, using a 30° easterly declination. Measurement was by Topafil and slope corrections were determined by the use of a clinometer.

Stations were marked with blue flagging and lines were marked with red flagging. The white thread from the Topofil gave excellent line guidance.

At the same time as the line was marked, soil samples were taken as described under Geochemistry and the relative vertical magnetic intensity was recorded as described under magnetics.

GEOLOGY

The rocks of this area belong to the Slide Mountain Group of Mississippian-Permian age according to the Geological Survey of Canada maps 11-1961 and 2-1962. They are characterized by basaltic pillow lavas, andesite and related pyroclastics. Minor argillite, chert and greywacke are present.

The meager bedrock exposed on the property consists of aphanitic, light to dark green andesite. It is massive in outcrop, exhibiting no preferred orientation. Despite rather substantial gossan in spots, there is very little pyrite present. On the baseline at 82 N, some fragmentals were noted. Chloritization is the only alteration present. Also on 82 N and at 115 E a medium grained gabbro with euhedral feldspar crystals and 1% fine pyrrhotite and a trace of chalcopyrite occurs. This strikes southward

and appears as a coarse grained gabbro with minor pyrrhotite 400 feet to the south. The contact is gradational. An isolated outcrop of coarse grained gabbro is found 1400 feet further southwest (64 N, 14 E). Weathering and gossan are prominent but it is nearly devoid of sulphide. Testing with a magnet indicated only a small amount of magnetism present.

At the north end of NICK 2 Claim, is a massive, medium-grained gneissic diorite, exposed as a south facing scarp on the northeast shore of the lake. This is part of a larger mass which outcrops on the northwest shore of the lake. It appears to be younger than the preceding rocks.

Between the two, in the vicinity of the Final Post for NICK 1 and 2 (114 N, 0E) the soil is almost black. A small rubbly outcrop of black carbonaceous quartzite occurs. In hand specimen it resembles coke. The material contains a few thin quartz-carbonate veins.

A linear depression along the creek and through the length of both Reed Lakes, is probably a fault. The amount and direction of displacement is not known.

The Quaternary is represented by glacial till, sand and gravel, some of which has been smoothed to form drumlins elongated in a NNE direction. The west part of the property consists of kames and terminal moraines, resulting in a series of short sharp ridges and hummocks. Angular rubble, where found, is considered to be near its source and a notation has been made of some of it on the geological map.

Four rock specimens were analyzed for copper and nickel. The highest copper assay was 0.03%, while the highest nickel assay was 0.02%. The

location and individual results are also shown on the geological map.

A short distance north of the claims, float was found that reportedly contained 0.14% Ni and 0.32% Cu.

GEOCHEMISTRY

A total of 921 soil samples were taken, all within 20 feet of the points marked on the grid. Samples were taken with a mattock. Details of the slope of the ground, depth, colour and texture of the sample, the soil horizon and probable origin were all recorded on a geochemical sample data sheet.

The "B" soil horizon was aimed for and largely obtained. It is mainly sand and silt with minor gravel or organic material. Samples were enclosed in a high wet strength kraft paper bag supplied by Min-En Laboratories of North Vancouver, B.C. They also did the screening and analysis.

The copper and nickel content of each sample was extracted by a hot acid leach. The amount of metal was determined by atomic absorption measurement. The results are recorded on Geochemical Analysis Data Sheets, copies of which are appended.

Map 93-J-14-A3 is the plot of the copper values so obtained and Map 93-J-14-A4 is the plot of the nickel values. Figures 2 and 3 are frequency histograms of the copper and nickel values respectively. They also show the median, background and threshold values determined from inspection of their logarithmic probability charts.

The copper values are generally low, 86% of which are in the background range of 50 ppm or below. 96% are below the threshold value of 90 ppm. The highest value obtained is 335 ppm. Values are outlined on the map by form lines at these two levels.

The largest area of above threshold values is centered at 88 N, 107 E where six samples indicate a length of 600 feet by approximately 200 feet wide. This is enclosed in an envelope of lower values which are still above background (49 ppm) but below the threshold (89 ppm). Both have a general N70°E strike. Only one other area has three samples above the threshold value. The remaining values are scattered throughout the map as isolated occurrences.

The nickel values are likewise low. The highest value obtained was 280 ppm. 85% of the samples had values in the background range (below 50 ppm) and 95% below the threshold values used (70 ppm). Above threshold values are even more scattered than were those for copper. Two areas, each containing four samples above threshold, are the greatest concentrations. They are centred at 100 N, 113 E and 96 N, 117 E. These lie within a large irregular east - west striking envelope of values which range between background (below 50 ppm) and threshold (70 ppm). It roughly coincides with the areas of better copper values.

From 80 N to 54 N nickel values are essentially low and uniform, with only two small exceptions.

MAGNETICS

A ground magnetic survey was run at the same time as the soil samples were taken. Map 93-J-14-A5 is a contoured plot of the values obtained and corrected for diurnal variation.

Lines were nominally spaced 200 feet and stations on them 100 feet apart, the same as for the soil sampling. Where it was deemed advisable, additional readings were taken to give 50 foot station intervals.

The instrument used was a McPhar M-700 magnetometer. It measures the vertical field, using the flux-gate principle. On its most sensitive scale, it can be read to an accuracy of 5 gammas.

The date and time, scale range and meter reading were recorded at each station. The baseline was traversed in both directions as rapidly as possible at the beginning of the survey. The values for each station served to tie in each cross-line and to correct for diurnal variation.

Relative values ranged from a high of +1140 to a low of -780 gammas. The map is contoured at 200-gamma intervals. For emphasis, only the -200 and +200 gamma areas are colored.

From 74° N south, the values are relatively even and low. From 76° N to 104° N the values are uneven. The north end of the property is again relatively even but at a greater magnetic intensity. This agrees in substance with the aeromagnetic contours shown on G.S.C. Geophysics Papers 1562 and 1563.

Some contours cross the map parallel to the lines run. It is likely these reflect some condition of reading which has not been filtered out, rather than some influence of the rocks beneath.

DISCUSSION

The limited amount of rock outcrop indicates only a small amount of pyrite and pyrrhotite present. The gabbro is only weakly magnetic and the remaining rocks are even less so. The overall lack of magnetic relief does not provide a basis for extrapolation of the known geology.

It would appear that the pattern of magnetic intensity is influenced by erratic material from outside the claim area and emplaced by glacial action. The great relief at 64 N, 102 E is due to some near surface, polarized material not spotted during the mapping.

Almost as erratic as the magnetic readings are the patterns developed by the soil geochemistry. The possibly anomalous areas are largely but not completely to the north of the lightly mineralized area. Thus some of the values may have been pushed north by ice movement. The surface of the ground, being quite hummocky with glacial material, would tend to give an uneven geochemical pattern.

CONCLUSIONS

There is little to indicate possible economic mineralization. While pyrite and pyrrhotite have been found in very small quantities, they contain only minor quantities of nickel and copper. It is unlikely that further work would be more encouraging.

STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

I, Bertram Taylor, of the District of North Vancouver, in the Province of British Columbia, hereby certify that:

1. I am a geologist, residing at 1981 Hyannis Drive
North Vancouver District,
British Columbia
2. I graduated from the University of Saskatchewan in 1941,
with a degree - Bachelor of Science in Geological
Engineering.
3. I am a member of the Corporation of Professional Engineers
of Quebec (1952) and of the Association of Professional
Engineers of the Province of British Columbia (1971).
4. I am a member of the Canadian Institute of Mining and
Metallurgy (1964) and of the Geological Association of
Canada (1953).
5. I have practiced my profession as a geologist for 32 years
in Quebec, Newfoundland and British Columbia.
6. The present report is based on work performed on the
NICK Claims - OCTOBER 5th - 15th, 1973 and study of the
references referred to.
7. The examination was made and this report written as part
of my employment by EL PASO MINING AND MILLING COMPANY.
