ASSESSMENT REPORT

1974 GEOCHEMICAL AND GEOLOGICAL REPORT

ON

SOL

THE SOL 1 TO 40 MINERAL CLAIMS

MT. McQUILLAN AREA

ALBERNI MINING DIVISION, BRITISH COLUMBIA

LATITUDE: 49° 06'N - LONGITUDE: 124° 36'W

N.T.S. 92F/2

92F/2E

JANUARY 15, 1975

T.E. KALNINS, B. Sc.
D.L. COOKE, Ph.D., P.Eng.

Period of Work

June 3, 1975 to October 18, 1974

TABLE OF CONTENTS

SUMMARY AND CONCLUSIONS

1. The Sol #1-40 claims were staked on Mt. McQuillan, 12 miles southeast of Pt. Alberni, B.C. to cover the precious metal rights within a section of the E and N Railway grants.

2. Detailed mapping, prospecting, soil sampling was done on the property from July 29 to September 23, 1974.

3. This work located widespread low-grade copper mineralization in Paleozoic volcanics and associated Jurassic and Tertiary intrusions. The soil geochemistry is adequately explained by the mineralization located on the property.

4. The mineralization consists of pyrite and pyrrhotite disseminations and fracture fillings. Minor amounts of chalcopyrite and molybdenite occur mainly along northeast trending fractures and quartz veinlets within the iron sulphide zones.

5. Geochemical anomalies outline three zones of copper-molybdenum mineralization. The best anomaly is centered on line 8S and measures 1200' by 1200' laterally and 1000' vertically. The ruggedness of the terrain prevented thorough soil samplings in this area. Further work is warranted.

INTRODUCTION

This report describes a copper prospect at Mt. McQuillan, 12 miles southeast of the seaport of Alberni, B.C. The report is based on field investigation by T. Kalnins and assistant D. Cary from July 29, 1974, to September 23, 1974. The work was supervised by D.L. Cooke of Cominco Ltd.

This year's program included line cutting, soil sampling, detailed geological mapping and prospecting. The geological and geochemical data are presented on maps at a scale of 1" = 400 ft.

PROPERTY AND OWNERSHIP

The Mt. McQuillan property consists of approximately 5500 acres containing base metal rights on a portion of the Esquimalt and Nanaimo Railway grant. The Sol 1-40 claim group was located to protect the precious metal rights. Several Crown granted claims, not held by Coast Copper, also lie within the area. The designated rights of the area under investigation have been assigned to Coast Copper through an agreement with Can Pac Minerals and Pan Canadian Petroleum.

Claim Data:
Name: Sol #1-40; Record Nos: 20383-20422; Due Date: Jan. 16, 1975.

.../2

LOCATION AND ACCESS (Figure 1 MQ-74-1)

The property is located at 49°06' north latitude and 124°36' west longitude, 12 miles southeast of Alberni, B.C. The claims cover Mt. McQuillan and a short range extending northerly between China and McQuillan Creeks.

Access is by helicopter from Pt. Alberni. Two branches of a logging road from Pt. Alberni terminate on the northern end of the property, but the last few miles are washed out and overgrown.

PHYSIOGRAPHY

Rocks are well represented by many outcrops in the area.

The claims are situated in very rugged terrain that varies in elevation from 1900' A.S.L. at McQuillan and China Creeks, to 5280' A.S.L. at Mt. McQuillan. Most of the work was done between 4500' and 2500' from a base camp at 4200'.

The rugged terrain, with cliffs and 45 degree slopes caused traversing to be slow and difficult. Consequently, cutting of the control grid was reduced from the proposed 20 line-miles to 12 line-miles.

Weather was excellent during the months of August and September. However, due to a long and late winter there was much snow on the ground at higher elevations during August, and patches of snow remained in September.

Both slopes of the main ridge are drained by numerous small creeks, most of which become dry after the snow run-off.

HISTORY

Placer gold mining in the China Creek area dates back to the turn of the century. There are 7 old underground workings within 2.5 miles of Mt. McQuillan, of which 3 produced a combined total of 8,000 tons of ore prior to 1948. The ore contained 3,226 oz. gold, 3,628 oz. silver, 626,556 lbs. copper, 7,817 lbs lead, and 4,478 lbs. zinc. The main producer was the Thistle Mine with 6,867 tons of ore that contained 2,667 oz. Au, 1,667 oz. Ag, and 626,556 lbs. Cu.

In 1962 Hunting Surveys did a regional aeromagnetic survey over the area. High magnetic values closely coincided with the outline of intrusive rocks.

During 1963-65 Gunnex Ltd. examined the old workings and covered the area by silt sampling and prospecting.

In 1973 Cominco Ltd. summarily checked the anomalous area and proposed to implement an exploration program during the 1974 season.

GEOLOGY

Regional Geology

Rocks observed in the area belong to the following classification: (A) Sicker Group Volcanics; (B) Jurassic Island Intrusions; and (C) Tertiary Intrusions.

.../Page 3

Muller of the Geological Survey of Canada in Paper 68-50, describes the Sicker Group Volcanics as massive dark green, brownish to maroon greenstones, fine or coarse breccias or laminated tuffs, that weather light green to light brown. Development of epidote, actinolite, chlorite and sericite indicate low-grade metamorphism.

Detail Geology (Figure MQ 74-2)

(A) On the property these volcanic country rocks comprise most of the outcrops. In this report they have been arbitrarily sub-divided into three units. Unit 1 is exposed mainly on the east slope of the ridge, and it is a dark, massive felsitic andesite. In the northeast corner of the grid it includes unit 1a, a 400-foot wide band of purplish, fragmental volcanics. Probably banding of tuffaceous material occurs at 8N + 19E. The NE strike and vertical dip of this unit coincides roughly with the main set of fractures. Banding also occurs at 28N + 8W, where the attitude is $010^{\circ}/65^{\circ}$E.

Unit 2 which underlies mainly the ridge and the west and north parts of the grid system is a hybrid (migmatite) andesite-diorite member. It is often gradational between an andesite and medium grain mottled diorite. It is greener in colour than the andesite and contains more of the metamorphic minerals. This hybrid rock is occasionally in contact with younger intrusions of fresher-looking diorite and narrow andesite dikes.

(B) An intrusive unit underlies Mt. McQuillan peak and consists mainly of diorite. The rock is relatively unaltered, blocky, light grey and coarse grained. Isolated outcrops may be amphibolitic. Small areas of these intrusives are exposed at Mt. McQuillan and at about 42N + 6E. The Mt. McQuillan diorite exposed above 4300 ft. elevation is coarsely "brecciated" by a multitude of narrow aplitic dikes.

(C) Quartz-feldspar porphyry stocks, dikes and/or sills (Unit 4) outcrop about 4S/E, 12N/E and W, 20N/NE, and line 36N/E and W. They range in width from about 4' to a substantial body on line 36N which is more than 500 ft. wide. Unit 4 includes some finer-grained rhyolitic members (4R). These rocks commonly exhibit some kaolin and sericite alteration products.

STRUCTURE

The oldest structural elements in the area are northerly trending axial uplifts and folding that includes Sicker Group volcanics. The oldest set of steep faults strike 10° - 20° NNW and provided structural control for the island intrusions. On the property a set of fractures coincides with this trend, as do the diorite outcrops of Unit 3. The main Tertiary faulting trends northwesterly, but subsidiary faults strike northeasterly. The latter development is the main structural feature on the property. Steeply dipping faults and fractures strike from 020° to 070°, but the main set is at about $050^{\circ}/70^{\circ}$ SE.

MINERALIZATION

There are three zones of low-grade mineralization that are substantiated by geochemical results. These are centered at 8S, 16N, and 36N. Chalcopyrite occurs frequently in these areas, but in isolated and minute amounts together with abundant pyrite and pyrrhotite.

.../Page 4

The three zones are similar in most respects. The northeasterly trending fracture system appears to have controlled introduction of quartz-feldspar porphyry dikes, a few mineralized quartz veins, and many mineralized quartz veinlets and joints. The zones are conspicuous by their rusty appearance. The host rocks are andesite volcanics and porphyry dikes. Very little metallic mineralization was detected in the diorite and the purplish volcanics.

Total metallic sulphide mineralization may be up to 5% but most of it is pyrite and pyrrhotite. Some effects of leaching appear at the surface. The low copper in the two northern zones, may indicate that the chalcopyrite occurs mainly in thin fractures and quartz veinlets within the volcanics. In the porphyry dikes sulphides are disseminated in the matrix. Molybdenite is occasionaly visible, and minor gold and silver are also indicated.

GEOCHEMISTRY

A soil survey was carried out on 12 miles of lines which were laid out by compass and chain survey. Iron-enriched B-horizon soil was sampled from about 6-inch depth, at 200-ft. intervals on lines 400 ft. apart.

The soils were dug with a narrow iron shovel and placed directly into Kraft paper sample bags. A total of 287 samples were collected and sent for analysis to the laboratory of Bondar-Clegg & Co. Ltd., North Vancouver, B.C. where Cu, Mo and Zn content was determined by hot aqua regia extraction and atomic absorption measurement.

Results (Figures MQ 74-3,4 & 5)

Copper values range from 2 ppm to 2100 ppm, zinc from 2 ppm to 480 ppm, and molybdenum from 0 ppm to 18 ppm. From inspection of the respective frequency distribution plots for copper, zinc and molybdenum, the following significant levels were established:

	Cu	Zn	Mo
Background	50 ppm	40 ppm	2 ppm
Anomalous (threshold)	150 ppm	100 ppm	5 ppm
Highly anomalous	400 ppm	-	-

The geochemical anomalies reflect the dispersed nature of minor base metal mineralization. Most frequently the anomalies are directly related to visible mineralization, or in overburden that is bounded by unmineralized outcrops. The three main anomalous zones are generally coincident with known mineralization centered on Lines 36N, 16N, and 8S. The strongest anomalies obtained by Gunnex are based on high copper values in streams draining northeasterly from the property, particularly from the 8S zone. This suggests that some of the smaller and less intense soil anomalies, which appear open because of insufficient sampling, may be of isolated nature and low economic potential.
