__ANGUS G. MacKENZIE MINING CONSULTANTS LTD.__

INTRODUCTION

Angus G. MacKenzie Mining Consultants Ltd. were approached by Mr. John Isima of Banff, Alberta on March 23, 1977 regarding a mining property held by Mr. Isima in the Terrace, B.C. area. A report on the Annette Claims, made by Richard S. Westbury dated July 28, 1976 was left with us along with a number of assay certificates that post-dated the Westbury report. Mr. Isima had, apparently found by way of chemical analyses, that the fractured bedrock and the alluvial sands and gravels lying on the bedrock, contained an interesting percentage of titanium (up to 1.15%). Mr. Isima's main interest at this time was to determine whether the titanium was present as ilmenite or rutile. At the same time Mr. Isima made tentative arrangements for our firm to make an examination of the claims as soon as possible after the snow had cleared.

In the meantime the pulps from samples submitted to Loring Laboratories on sand samples collected by Mr. Isima and assayed in January 1977 were obtained and several of these were given to the Department of Energy Mines and Resources, Federal Government, who reported, in part, as follows on May 27, 1977:

"Two pulverized sand samples were submitted to ascertain whether their high titanium content was due to ilmenite or rutile. ---- a diffraction pattern was made of the residue, this reveals anatase and some rutile, but <u>no ilmenite</u>." ---- The entire report is appended as part of this report.

Based on this result, Mr. Isima decided to conduct a detailed sampling program on the claims and requested our firm to make an examination at the same time. A tentative date was arranged, and this report is based on this examination and the results of assays obtained from some 31 samples cut in large lots on three lines covering the exposed gravels and sands on the northern part of the Annette Claims. The examination was carried out May 14, 15, 16 and 17, 1977.

ANGUS G. MacKENZIE MINING CONSULTANTS LTD.

LOCATION ACCESS AND STATUS OF CLAIMS

The property is located approximately 10 miles east of Terrace on Highway 16 thence east on a logging road put in by Canadian Cellulose Limited, a distance of about 5.5 to 6.0 miles. The road is well maintained up to the turn off down to the creek level, where several small mud slides have blocked access to the Annette Claims area. One can presently get to within one-half mile of the Canadian Cellulose bridge which is located at about the center of the center line of the two most northerly claims. See Index Map - Claims Location, attached as Figure 1

- 2 -

The claims are registered as Annette 1 to 4 recorded Nos. 130721/24 and Annette 5 to 8 recorded Nos. 13,291/94. They are located in the Omenica Mining Division and according to Mining Receipt No. 64 93438E all claims are in good standing for two years from July 22, 1976.

GENERAL COMMENTARY

Since Westbury's examination the various assays have indicated that titanium might be the mineral to be looking for, rather than copper and/or gold. With this in mind, the sampling program, already referred to, was completed and indications are that the gravels and sands overlaying the bedrock on the Northern Annette Claims do contain an appreciable amount of titanium in the form of anatase and rutile. A sketch map of the area indicating the approximate location of these samples is attached as Figure 2 in this report.

Assay reports from independent laboratories, namely Loring Laboratories Ltd. in Calgary and X-Ray Assay Laboratories of Don Mills, Ontario, on what were considered to be duplicate samples are not at all comparable. See certificates appended, Loring Labs File No. 13241 dated May 27, 1977 and X-Ray Labs File No. 1480 dated May 31, 1977.

ANGUS G. MacKENZIE MINING CONSULTANTS LTD.

It will be noted that Loring Labs show <u>NO</u> titanium for samples 2 to 19 inclusive and not less than 0.57% for the balance. Whereas X-Ray Labs show values from a low of 0.26% to a high of 0.51% on all samples. Loring reports as titanium oxide while X-Ray reports as percentage titanium metal.

On first glance it looks like Loring Labs forgot to throw the switch on the first 18 or 19 samples, and that there is some error in the multiplier in either the X-Ray results or Lorings.

Since analysis on all previous samples and spectographic analysis indicate a grade of better than 0.5% titanium metal, we will assume that the error in assaying as described is essentially correct and that if we take the X-Ray results for the first 18 or 19 samples and multiply them by a factor of 2, we will arrive at a figure comparable with the Loring Labs results for the balance of the samples, and obtain an average assay that is comparable to the results obtained from two composite samples sent to Loring Labs, File No. 13231 dated May 26, 1977 of 0.64% titanium (as T_1O_2), see assay certificate appended. The spectographic analysis on the same sample sent to Can-Test Labs, File No. 1860 dated June 2, 1977 gave a result of 0.5% titanium.

The straight arithmetic average of the 31 samples submitted to both labs and corrected as indicated is 0.72% titanium.

For the purposes of this report we will assume that this value 0.72% T_1O_2 is the content of the sands and gravels in the examined area by us.

In the meantime both labs have been requested to rerun all 31 samples.

SAMPLING PROCEDURE

Mr. Isima had Gerry Vene and George Buat assisting him in the sampling program. At first, a post hole auger was tried but found to be unworkable and the sampling was done by a pick and shovel. Three main lines of sampling were

ANGUS G. MacKENZIE MINING CONSULTANTS LTD.

- 3 -

laid out. See Figure 2. All samples were in the order of 10 lbs. in weight. Two composite samples were taken from each of the sample sites and assayed separately. These samples were taken to Calgary directly by A.G. MacKenzie and delivered to Loring Laboratories Ltd. Certificate of analysis is appended. The balance were taken to Terrace and shipped to Mr. Isima at Banff where they were split and duplicate samples sent to independent labs for analysis. The results have already been discussed, in light of their indicated values.

GENERAL DISCUSSION_ON_TITANIUM

Titanium has only recently become a useful metal. Its greatest use is in paint pigment. There are many other uses found for the pure oxide in such fields as in toilet articles, linoleum, white inks, coloured glass, pottery glazes and tinting artificial teeth, for dyeing leather and cloth. Metallurgically it is used as a ferrocarbon titanium in high speed tool steels and in chrome steels. Many new and innovation uses are being found for titanium oxide in various industries. Titanium ore as ilmenite that contains 54% T₁O₂ sells for around \$55./ton. In the form of rutile and/or anatase it currently markets for \$510.00 per stock ton guaranteed, delivery within 12 months Titanium slag at 70% sells for \$102.00 per long ton. (E.M.J. May/77)

The ore minerals of titanium are rutile, ilmenite and titanite. These minerals are heavy and resistant to weathering and consequently are found frequently in placer operations or as placer deposits. Rutile ores as marketed contain 92 to 98% titanium oxide, while placer ilmenite usually run from 51 to 60% titanium oxide. The ore after concentration is melted in electric furnaces and the fused product is leached with sulphuric acid and the titanium oxide so produced is further purified.

There is, to our knowledge, only one producing titanium property in Quebec, and the titanium ore (ilmenite) is metallurgically treated at Sorel.

ANGUS G. MacKENZIE MINING CONSULTANTS LTD.

- 4 -

This ore contains from 35 to 40% titanium oxide. Larger deposits are reported in Russia with about 16% titanium. Black sands in Japan are said to contain ten billion tons with a content of from 20% to 30% titanium and 0.6% vanadium.

Most of the worlds supply of titanium is iron from beach sands, those of Travaucore and Quilon, India, giving over half the world production. Here the sands contain 50 to 70% ilmenite along with monazite, zircon, rutle and garnet as well as other minerals of no commercial value.

It should be noted that Quebec Iron and Titanium Corporation have reserves of around 100,000,000 tons of ilmenite containing over 82% <u>combined</u> <u>iron and titanium oxides</u>. From this resource the company operates nine smelting furnaces at Sorel, Quebec, with a daily capacity of 5,000 tons, for a production of approximately 860,000 tons titanium slag and 600,000 tons of high grade iron per year. A subsidiary company operates a metal powder plant at Tracy, Quebec and substantial expansions to this plant were made in 1974. The plant capacity was increased to 2,100,000 tons of ilmenite ore per annum. Up to December 1973 Quebec Iron and Titanium had produced 21,082,232 tons of ore. The company is owned two-thirds by Kennecott Copper Corpoation and one-third by New Jersey Zinc Co.

Beach Sands in India currently supply about one-half the world production and contain up to 70% ilmenite, along with other economic minerals, such as monazite.

In other words, we are trying to show that a deposit containing titanium, in whatever form, would have to be <u>extremely large and contain between</u> <u>15 and 20 percent + Titanium (metal) in order to be competitive in today's</u> <u>market.</u> The best results of the recent sampling program average only 0.72% T_iO₂.

METALLURGICAL TESTS

A bulk sample weighing approximately 125 lbs. (wet) was sent to Kipp Kelly in Winnipeg for dry separation tests. Their total report on these tests is appended.

The results of four sized tests on this 'sand' material indicate that it would be necessary to

- (a) either size the raw dry material so that only-76 or -140 mesh material was treated, or
- (b) crushing the entire feed to a -40 mesh product.

In either case the economics of sizing, one way or the other, would require the treatment of an extremely large quantity of raw material to provide a suitable concentrate. The ratio of concentration would be excessive, and the concentrate produced is highly magnetic.

No assays were run on the Kipp Kelly concentrates as the volume was too small to give a realistic result, and as pointed out above, the ratio of concentration would be prohibitive.

Another serious difficulty arises when one considers the regulations, of the B.C. Government. According to these regulations Kleanza Creek lies <u>outside</u> the only area in the Terrace District that is designated, as open to Placer Mining, and the type of deposit on the Annette Claims would in all probability be considered a <u>Placer</u> as it is made up of gravel and sand. However it must be remembered that the original staking was done on the strength of the metal content in a shear zone. Assays from this shear zone indicated up to 1.0% titanium oxide.

is not clear. If the area were worked as a source of clean washed gravel and/or sand and a mineral by-product extracted by whatever suitable means, would it still be considered a Placer operation?? These questions only the B.C. Government can answer and will depend entirely on their definition of a Placer and their interpretation of the definition of a Mineral (other than Gold).

CONCLUSIONS AND RECOMMENDATIONS

Based on the prevailing world market requirements, it appears that the titanium content of the gravels and rock on the Annette Claims is too low to become an economic entity. The consideration of the retention of washed gravel for alternate disposal is another matter, but it too has definite market limitations and a low unit price f.o.b. the mine site.

From the standpoint of regional and local geology, the area is interesting and should receive more careful prospecting, but this would entail a fairly large program to be conducted outside and surrounding the present Annette Claims. A purely grass roots type of reconaissance venture. Our considered recommendations for the gravel in the Annette Claims simply boils down to the cold hard fact that the contained mineral of interest titanium is not present in sufficiently high enough quantity to make the prospect viable. We would suggest therefore that, for the present, and until higher values can be located in the area, all work in connection with the possible production of these gravels for titanium be suspended.

As previously suggested the area is structurally interesting and it is now, more or less, opened up by access roads, etc. that wider search be made for other mineralization. The potential for a good copper-gold prospect seems to be the best bet. Areas of major faulting should be closing prospected and some attempt made to put together a structural picture of the

- 7 -

area. Any further work should be predicated only on positive results from the suggested area survey.

DECLARATION OF QUALIFICATIONS

OF

ANGUS G. MACKENZIE. P. ENG., MCIM.

- I. Angus G. MacKenzie hereby certify that I am a Consulting Mining Engineering - Mining Geologist. I am a graduate (B.C) in Mining and Metallurgy of Nova Scotia Technical College, Halifax, Nova Scotia and I have taken Post - Graduate economic Geology at Dalhousie University.
- 2. I have spent the past thirty five years in the Minerals Industry as a Mining Engineer and/or Mining Geologist and have maintained responsible positions in these fields at mining properties in Newfoundland, Nova Scotia, Quebec, Ontario, Manitoba, Saskatchewan., Alberta, British Columbia, the Yukon and Northwest Territories. I have also had considerable experience in the United States, Mexico and Southeast Asia.
- 3. I am a Registered Professional Engineer in the Province of Alberta and have held memberships and/or licenses to practice from Associations of Professional Engineers in the Yukon, Manitoba, Saskatchewan, Nova Scotia, Quebec and British Columbia. I was also registered in the State of Colorado, U.S.A.
- 4. I have no personel interest, directly or indirectly, in the property herein reported on nor in the securities of ANM CONNECTED COMPANY and/or its associated companies, nor do I expect to receive any such interest.

This report may not be reproduced in whole or in part without the written permission of Angus G. MacKenzie, P.Eng.

5. This report is the direct result of an examination by Angus G. MacKenzie Mining Consultants Ltd. and a review of all reports and other pertinent information, on the property.

Mineralogical Analysis

SUBJECT

Two pulverized sand samples were submitted to ascertain whether their high titanium content was due to ilmenite or rutile. This was not determinable in the whole rock because the titanium X-ray diffraction lines are masked by those of the silicate matrix. The samples were predominately quartz, feldspars and micas, and the removal of these silicates with hydrofluoric acid concentrated the titanium fraction. A diffraction pattern was made of the residue; this revealed anatase and some rutile, but no ilmenite. It is possible that some of the titanium is present as a silicate, (for example, sphene, CaTiBIO₅) which would be destroyed by the acid. A heavy mineral fractionation of the sand would be required to determine the presence of titanosilicates.

Titanium is found in the magnetic portion of sample thus indicating that it is present as titaniferous Magnetite.
