INTRODUCTION AND SUMMARY

The CK claims are located some 150 kilometers north of Kamloops, B.C., 8 kilometers south east of Wells Grey Park, as indicated on the accompanying location plan 132-78-1. The lines surveyed are indicated on accompanying claim map 132-78-2.

During the period May 19 to May 28, 1978, a Cominco geophysical crew completed some 8 line kilometers of multi separation induced polarization survey and some 9 line kilometers of total field magnetics survey. On June 6 some 2.5 line kilometers of VLF EM survey was done.

The purpose of the survey was to try to define a geophysical target that could represent the source for mineralized boulders in the survey area.

This report describes these geophysical surveys and discusses the results obtained.

LOCATION AND ACCESS

The CK claims lie at approximate geographic coordinates of 51°55'N latitude by 119°35'W longitude, and are in the Kamloops Mining Division.

Access is by highway No. 5 some two and a half miles north of Clearwater then by logging road along the west side of the Raft River to McClosky Creek.

GEOPHYSICAL SURVEYS

Magnetics Survey

The magnetic survey was done by Boris Lumm, geophysicist in training. A Scintrex MP-2 total field proton precession magnetometer was utilized. The instrument has a scale sensitivity of 1 gamma. The data was corrected for diurnal variation using the standard base and sub base station looping method.

Readings were normally taken at 25 meter intervals on cross lines 100 meters apart. The data is presented in contour plan form as accompanying plate 132-78-3.

VLF Survey

The VLF survey was also conducted by Boris Lummm, geophysicist in training. A Crone Radem VLF-EM receiver was utilized on the survey, with station NLK (Seattle, Washington at 18.6 KHz) serving as the primary VLF field. The dip angle of the resultant field and the horizontal component of the field strength were the parameters measured on the survey, and they are presented in profile form on the IP pseudo sections.

Readings were taken at 25 meter intervals on lines 1, 2, 5, and 6 North. The dip angle data is plotted so as to give a "left wave crossover" over a conductor.

Induced Polarization

G.J. Niemeyer, geophysical technician, was the party chief/receiver operator on the IP survey.

A Scintrex IPR-8 receiver in combination with a Huntex 7.5 KW motor generator/transmitter were deployed on the survey. The equipment measures the chargeability response in the time domain, employing a 2 second current on and 2 second current off alternating polarity square wave signal. The data plotted is the M_{232} value and the units are millivolts per volt. To convert to the more usual millisecond value (such as would be obtained with the IPR-7) the values should be multiplied by 0.7 for a "typical" decay curve. The reader is referred to the Scintrex manual for a more detailed discussion of this instrument.

The pole-dipole electrode array was used on the survey, with an "a" spacing of 50 meters and "n" separation of 1, 2, 3, and 4. Readings were taken at 50 meter intervals on crosslines 100 meters apart.

The chargeability and apparent resistivity data is presented in standard pseudo section form on accompanying plates 132-78-4 to 132-78-13 inclusive.

DESCRIPTION OF RESULTS

Magnetics Survey

The total field magnetic data is presented in contour plan form on accompanying plate 132-78-3.

A magnetic high trends north north west across the survey area from 375E on line 0+00 to line 5+00N on the baseline, approximately as outlined by the 58600 gamma contour. This magnetic high is spacially coincident with high chargeability values, suggesting the IP anomaly is in part due to magnetite and/or pyrrhotite.

A subparallel and weaker magnetic high, extends from line 4+00N; station 2+50E to line 8+00N; station 2+00E and is also spacially coincident with high chargeability values. It is defined by the greater than 58500 gamma contour.

The strongest magnetic high detected on the survey is on line 4+00N at station 7+00E. This anomaly is part of a larger zone of high magnetic field strength (as outlined by the 500 gamma contour), that extends from 7+50E on line 1+00N to station 5+50E on line 6+00N. This magnetic high is spacially coincident with moderately high chargeability response.

VLF Survey

VLF coverage was obtained over the main IP anomaly on lines 1, 2, 5, and 6 North. The field strength and dip angle data is plotted on the pseudo sections for those lines.

Due to the steep hillside slope on which the survey was run, zero crossovers of tilt angle were not obtained. However by "eyeballing" the zero upwards and referring to field strengths, VLF conductors can be interpreted at: -

Line 1+00N: station 3+50E
Line 2+00N; station 2+50 to 3+00E

These VLF conductors are coincident with high chargeability and low apparent resistivity.

Less well defined VLF conductors were also detected on line 5+00N at 3+00E and from the baseline to 0+50W.

Induced Polarization Survey

The induced polarization (chargeability) and apparent resistivity data is presented in standard pseudo section format as plates 132-78-4 to 132-78-13 inclusive.

A strongly anomalous zone of high chargeability was detected to the west of the creek, and extends from line 1S to 8N. The anomaly is open to the north west. North of line 3N, the anomaly appears to form two separate zones (this is also indicated by the magnetics, with the western zone having the higher magnetic values).

Chargeability response is strongest on line 2N at 2+75E, with an n=1 value of 60 millivolts/volt. The VLF survey indicates a wide conductor between stations 2+50 to 3+00E, coincident with the chargeability high. The associated magnetic high is relatively weak on this line.

The next strongest response is on line 1N at 3+75E, with an n=1 value of 53 mv/v. The VLF survey indicates a conductor at 3+50E, and the magnetics survey shows a magnetic high from 3+25E to 4+00E.

These anomalies lie just upslope from mineralized boulders.

A moderate amplitude chargeability zone lies to the east of the creek. This zone is open to the east and to the south, and is spacially coincident with a magnetic high.

CONCLUSIONS

Portions of the CK claims were surveyed by multi separation pole dipole time domain IP, total field magnetics, and VLF electromagnetics in the Spring of 1978.

A strongly anomalous chargeability zone was detected west of the stream. The anomaly is spacially coincident with high magnetic field values, and on lines 1N and 2N with VLF conductors. As this anomaly is just upslope from mineralized boulders, it should be considered a good drill target.

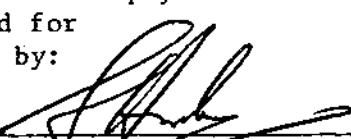

A zone of moderately anomalous chargeability response was detected to the east of the stream. It is also, at least in part, spatially coincident with high magnetic field values. No VLF data was obtained over this anomaly. It should also be considered a valid, but lower priority, drill target.
