х... Х. К

This report summarizes the field work done on Spanish Mountain, near Likely, B. C. during the first week of September 1977 and presents a brief outline of the regional geology and past history.

A total of 81 claim units were staked. These are the the Peso, Peso A to Peso F claims. Work was centered on the Peso Claim and this report is submitted for consideration for assessment work credits on the Likely Group (Peso, Peso B and Peso E Claims).

Recommendations for further exploration are given.

SUMMARY AND CONCLUSIONS

I. Gold is found in two types of quartz vein on Spanish Mountain. Narrow, discontinuous gash. veins strike at right angles to a major fault. Visible gold is common in these. Massive quartz veins strike approximately parallel to the major fault. Gold can be panned from these.

2. The main country rock is dark grey, fine grained phyllite. Quartzite occurs in places. These rocks belong to the Cariboo Group of Palaeozoic age which are host to gold deposite 30km to the north. Alteration by carbonatization and pyritization is widespread and pervasive throughout the area.

3. Soil geochemistry shows that analysis for gold will indicate gold-bearing quartz veins. High background values may indicate gold-bearing zones in the country rock.

4. The gash quartz veins appear to be too small and widely spaced to be economic. The more massive veins would require rehabilitation of the old adits and controlled sampling before an evaluation could be made.

-2-

 There is potential for zones of replacement within the country rock since:

- (a) Phyllite is a suitable host rock
- (b) A major structural break occurs in the area which may be related to the known gold showings.
- (c) Alteration is widespread, particularly the introductionof pyrite.
- (d) The phyliites appear to be geochemically anomalous with respect to gold and contain visible gold where altered adjacent to quartz veine.
- (e) Gold is associated with pyrite in the placers of Cedar Creek and Spanish Mountain. Gold was seen to be contained in (oxidized) pyrite.

6. It is recommended that a soil sampling program be conducted to search for replacement type gold deposits and further quartz vein systems. Soils should be analysed for gold, silver, copper and lead. Whether there is a correlation

٠

between gold and other elements could first be tested on the samples already collected. In view of the association of gold and pyrite, anomalous areas should be surveyed by IP methods to delineate conductors. The field time would be two months.

Respectfully submitted

A. R. Kittlejohn

A. L. Littlejohn, Geologist, September 30, 1977, Delta, B. C.

tinder The the section of

BACKGROUND

The area of interest is covered by N.T.S. map sheet 93A/11W and is approximately 10km southeast of Likely, B. C.  $(52^{\circ} 37^{\circ}N_{2}121^{\circ} 35^{\circ}W)$  on Spanish Mountain.

Small placer operations were carried out in this area during the 1860's but no large scale mining was done. Interest revived in the 1920's with production from Spanish Creek to the north and Cedar Creek to the south. Desultory placer work has continued to the present, including some workings on Spanish Mountain.

In the Cedar Creek and Spanish Mountain Camps the gold is coarse and well worn although in places it is rough. It occurs in Tertiary gravels lying on the plateau which have been only partially reworked by glacial action and recent stream action. The pay gravel is characterized by the presence of small cubic pseudomorphic crystals of limonite after pyrite. This is a feature of all the rocks observed on Spanish Mountain by the writer and suggests that the source may not be far away.

-5-

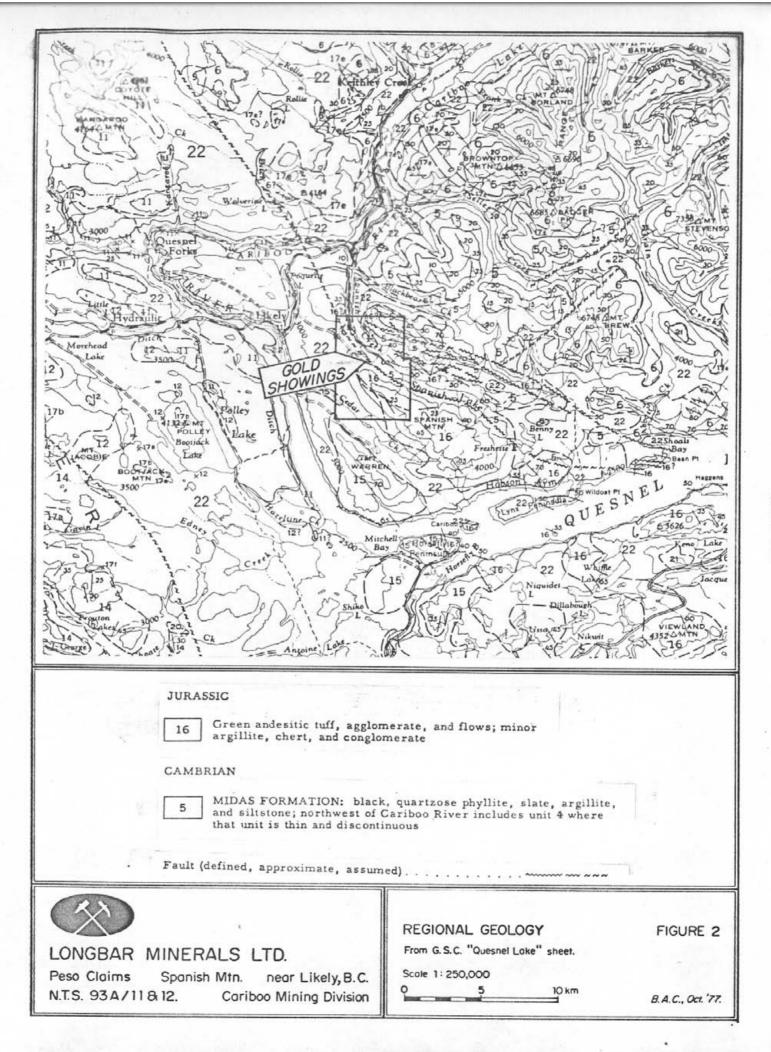

In the Spanish Creek camp the gold occurs in resorted gravels and is rather fine.

Gold-bearing quartz veins were discovered on the northeast side of Spanish Mountain in 1933. The veins vary from a few centimeters up to 0.8 metres in width. One sample from a vein 20 centimetres wide assayed 0.10 oz per ton in gold and 1.4 oz per ton in silver. This is comparable to the assays obtained on the present survey.

Fairly extensive work has been done on this area since 1933. Two adits were driven into sparsely mineralized quartz veins which are 2 - 5 metres thick. Up to 1947 several hundred feet of diamond drilling had been carried out in the area in search of mineralized quartz veins. The only significant mineralization was found in the narrow quartz veins which have been exposed by trenching at several places. Assays of <u>selected</u> samples of this type of vein gave values up to 5.88 oz per ton in gold and 32 oz per ton in silver. A 4 ton shipment of <u>selected</u> ore from surface cuts returned 8 oz.of gold, 40 oz of silver, 32 lb. of copper.

-6-

No significant work has been carried out since 1947 although local residents report intermittent activity.

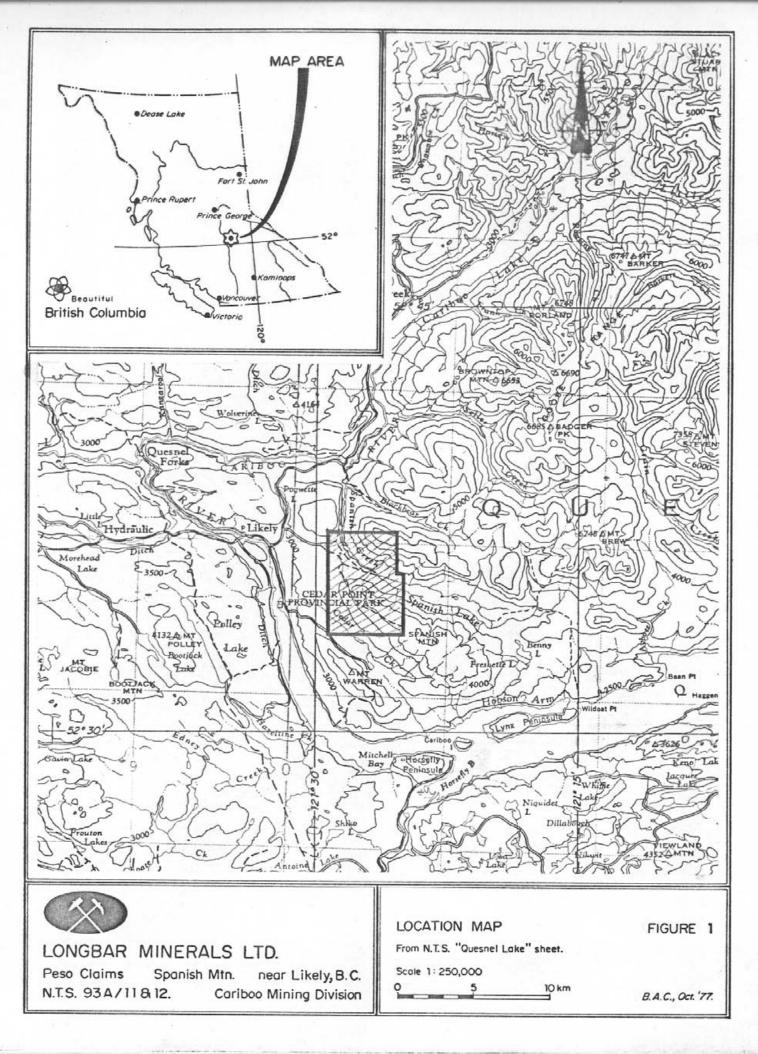

REGIONAL GEOLOGY

The main feature of this area is a major fault trending NW - SE, parallel to the main fold axis. At the west end of Spanish Lake this fault swings to a WNW - ESE trend and parallels the lake along the northeast flank of Spanish Mountain. A number of smaller faults are parallel to the latter section of the major fault on it's northeast side.

The fault separates Middle Jurassic or Cretaceous andesitic tuff, argillite, chert and conglomerate from Cambrian phyllite, slate and argillite. The latter lie on the north side of the fault and form part of the Cariboo Group which underlies the goldfields of the Yanka Peak area 30km to the north.

The gold showings on Spanish Mountain are found in the area where the major fault changes strike.

-8-

LOCAL GEOLOGY

The main rock type on Spanish Mountain is a dark grey, fine grained phyllite which is interbedded with impure quartzite horizons of varying thickness and extent. The strike is parallel to the major fault and the rocks dip moderately to the south. Dolomite occurs towards the crest of Spanish Mountain ridge. A medium-grained quartzfelspar dyke, striking NE - SW across the phyllites, was observed in a trench at 4,000 ft. elevation.

There are two systems of quartz veins. At 3,900 ft. elevation a vein varying in thickness from 1 to 5m csn be traced for 250m along the strike. It strikes E-W and dips 60 degrees south. A second vein lies 30 ft. below this and may represent a faulted portion of the main vein, since both are highly fractured, have the same mineralogy and the country rock at the contacts is highly sheared. The veins contain scattered patches of cubic pyrite (often altered to limonite) in open spaces and muscovite. Minor galene is also present. Most of the mineralization is at the contacts.

-9-

Gold was panned from this vein system, although none was observed. Two adits (now inaccessible) have been driven into these veins. At 4,200 ft. elevation there is another massive quartz vein exposed (partly by trenching) for 30m. It is about 8m thick and strikes NW - SE. It's attitude could not be determined. It is highly fractured and shattered and is aparsely mineralized with pyrite.

The second quartz vein system consists of a series of narrow ( 0.1 - 0.8m ) veins which strike NE - SW (approximately at right angles to the major fault) and dip 50 - 70 degrees to the west. Where exposed along road cuts and in trenches they are seen to be rather discontinuous, although one was traced over a length of 120m. They are generally spaced several metres apart and the thicker ones are tens of metres apart. At least 15 such veins were found over a 40,000 square metre area. The veins themselves represent a tiny fraction of this area. The veins appear to be gash veins, filling fractures in the country rock. Often they are highly fractured themselves.

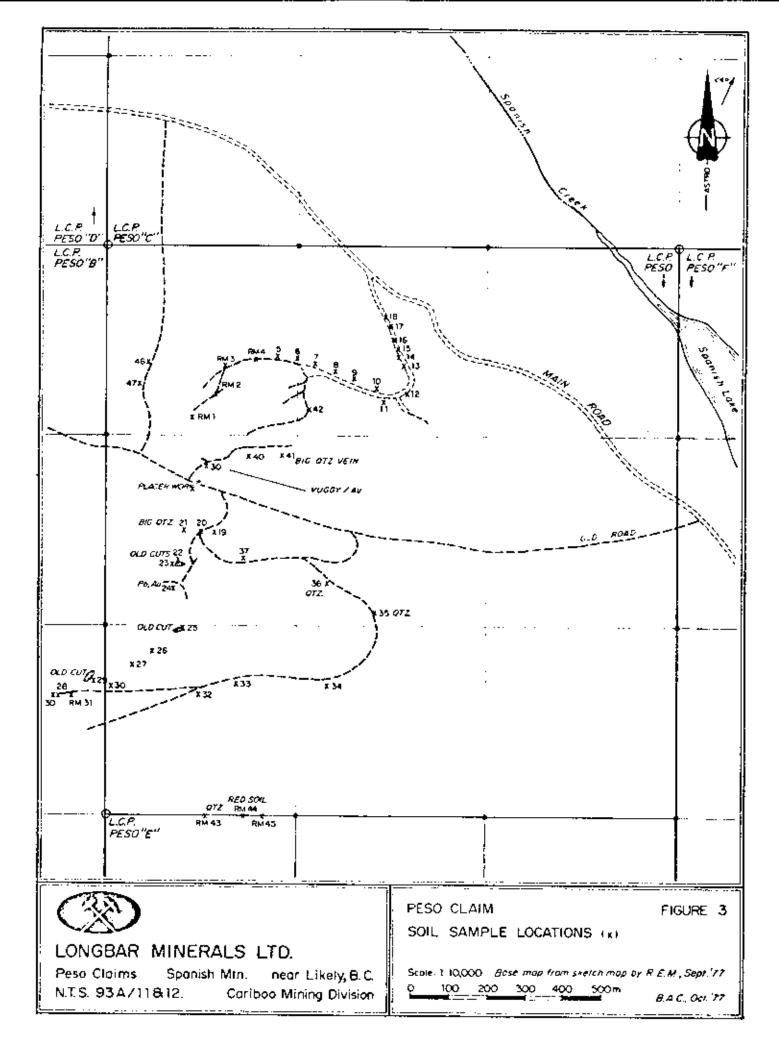

The veins are mineralized with gold, silver, pyrite, galena and tetrahedrite. Pyrite occurs in cubic and prismatic aggregates which have usually weathered out to produce a honeycomb structure. This feature is particularly evident at the contacts and extends into the wall rock for a few centimetres, especially if the rock is argillaceous. Many of the cavities are lined with quartz on which the pyrite striations have been imprinted. Thin flakes of gold are found within these cavities and occasionally gold can be seen embedded in limonite. Gold and silver can be panned from the quartz. Alteration in the area is pervasive and has affected all rock types. Pyrite cubes up to 3cm in diameter give the rocks a mottled appearance, especially the lighter coloured quartzites. In the phyllites, pyrite also forms small pods and stringers. Pyrite mineralization does not appear to favour one particular rock type. This type of mineralization is widespread, being found in argillites on the north side and east end of Spanish Lake. The association of gold and pyrite is evident in the quartz veins and in the placer workings of Cedar Creek. Pyrite usually has a thin coating of red haematite and more often than not is completely exidized to limenite. The presence of quartz limings in

-11-

the pyrite cavities suggests that some silicification has occured in association with the quartz veining, but this appears to be local.

A second type of alteration is carbonatization. Ankerite occurs as discrete, brown grains with oval or diamond - shaped cross-section in dolomite and quartzite and in the intrusive dyke. It adds to the already mottled appearance of the rocks. Carbonate minerals also occur in patches within the rock groundmass. It is suspected that rock noted as dolomite in the field, may in fact be highly altered quartzite or intrusive. A mariposite-like green mineral occurs in scattered patches, noticeable in the lighter coloured rocks.

-12-

SAMPLING:

-

Eight (8) rock samples were taken and assayed for gold and silver. One (1) rock sample was assayed for gold only. Five (5) rock samples were geochemically analysed for gold. Sixty (60) soil samples were taken, 13 were analysed for gold and silver, the remainder were analysed for gold only. Five (5) samples of narrow quartz veins and 3 samples of phyllite were taken by the writer. A further 6 rock grab samples were taken by R. M. Mickle. Table One lists the results.

-13-

Taken from north shore of Spanish Lake, all others from Peso Claim

-14-

The assays from the quartz veins are variable and range from 0.004 to 3.100 oz. per ton in gold and 0.07 to 0.75 oz. per ton in silver. Sampling bias in the large quartz veins is not known so that the high values may not be representative. However it is apparent that good values from the veins can be obtained. The gash-type veins, although they contain visible gold and assay up 0.275 oz. per ton appear to be far too narrow and widely spaced to be mined.

The phyllites are geochemically anomalous with respect to gold and silver. Sample P 3 assayed 0.04 oz. per ton in gold and 0.11 oz. per ton in silver. The lowest values were in sample SPLK #1 which has 0.005 oz. per ton in gold and 0.08 oz. per ton in silver. This sample was taken from the roadside on the north side of Spanish Lake where pyrite stringers and lenses have been introduced into the phyllites. Similar rocks were observed on the road on the south side of Spanish Lake, about 15km to the east of the claims. One or two small colours were obtained from several pans from this area. Sixty (60) soil samples were taken by R. M. Mickle. His sketch maps are appended. Of these samples, 37 are anomalous (>40ppb) and 12 contain more than 1000 ppb gold. Most of the highly anomalous samples were taken close to old workings or exposed quartz so that high values are not unexpected. The samples which were analysed for silver as well as gold turned out to be non-anomalous (RM 48-60). These were taken away from the known showings.

RECOMMENDATION & COST ESTIMATE

In view of the widespread occurences of gold in this area it is recommended that further work be undertaken to extend the gold-bearing zones. There is potential for replacement type deposits as well as additional quartz vein systems. The main target areas would be the areas adjacent (within 1 claim length) to the major fault. A reconnaissance soil sampling survey on 100 X 50 metre grid would provide information on this. Multi-element analysis of soils should be carried out since this is a "new" area and the geochemical characteristics of the soil are unknown. Anomalous areas should be surveyed by IP methods to delineate sulphide zones.

A cost estimate of such a program is given on the following page.

Campbell R. B. (1961) Quesnel Lake Map Sheet (93A/W)

CERTIFICATE

I, Alastair L. Littlejohn, of Vancouver, British Columbia, do hereby certify that:

I am a geologist with an office at 4882 Delta Street,
 Delta, B. C. V4K 2T8.

2. I am a graduate of Aberdeen University (1969) with a degree in Geology (B.Sc. Hons.) and the University of British Columbia (1972) with a degree in Geology (M.Sc.)

3. I have practised my profession continuously since graduation while being employed by such companies as Canada Tungsten Mining Corp. Ltd. and Amok Ltd.

4. I have no interest, either direct or indirect, in the properties of Longbar Minerals Ltd., nor do I expect to acquire any such interest.

1 h. Letteplas

(signed) A. L. Littlejohn, September 30, 1977 Delta, B. C.
