### INTRODUCTION

The THALIA property is located some 12 kilometers south of Aspen Grove, B.C., as indicated on accompanying Plate 147-78-1. The lines surveyed, in relation to the claims, are shown on Plate 147-78-2.

During the period August 10-14, 1978, a Cominco geophysical crew completed some 5.6 line kilometers of multi separation induced polarization survey over portions of the THALIA claims. One line was surveyed on the "West Grid" and the remaining six lines were surveyed on the "East Grid".

This report describes this induced polarization work, presents the data, and discusses the results.

### LOCATION AND ACCESS

The THALIA claims are approximately centered at geographic coordinates  $49^{\circ}50'N$  latitude by  $120^{\circ}35'W$  longitude, and are situated immediately southwest of Bluey Lake.

Road access to the property is gained by turning east onto a good gravel road from highway number 5, some 12 kilometers south of Aspen Grove.

### GEOLOGY

The THALIA property is an alkaline porphyry copper prospect located in the Aspen Grove complex. It is underlain by a sequence of basaltic pyroclastic rocks intruded by small dioritic and monzonitic dykes and stocks. Chalcocite mineralization, associated with calcite, epidote and clay alteration in fractured diorites, has been identified in trenches on the "East Grid".

#### INDUCED POLARIZATION SURVEY

The survey was conducted under the direction of A. Scott, geophysicist, and G. J. Niemeyer, geophysical technician.

The east grid was surveyed using a seven man crew with two receivers operating simultaneously. (Read n=1 and 3 then both move to read n=2 and 4). The single line surveyed on the west grid was surveyed with a four man crew.

Scintrex IPR-8 receivers, in combination with a Huntac 7.5 kw motor generator/transmitter were used on the survey. This equipment operates in the time domain, employing a 2 second current on/2 second current off alternating square wave. The chargeability (IP) values plotted are the M<sub>232</sub> values, and the units are millivolts/volt. To convert to the more common millisecond value (such as would be obtained with the older model IPR-7), the numbers should be multiplied by 0.7, for a "typical" decay curve. For a more detailed discussion of this instrument, the reader is referred to the Scintrex manual for the IPR-8.

The pole dipole electrode array was used on the survey with an "a" spacing of 50 m and "n" separations of 1, 2, 3, and 4. The current electrode was kept to the west of the potential dipole.

The apparent resistivity data is given in units of ohm meters. The values were calculated from the relation:

$$\text{apparent resistivity} = (V/I) \cdot K$$

where V is the voltage across the potential measuring dipole due to a transmitted current I, and K is a geometric factor dependent upon the "a" spacing and "n" separation.

#### DESCRIPTION OF RESULTS

The induced polarization (chargeability) and apparent resistivity data is presented in standard pseudo section format as Plates 147-78-3 to 9 inclusive.

Plate 147-78-3 gives the results of the line surveyed on the west grid. A weak anomaly is located at station 125E. The  $n=1$  value is 6.0 millivolts per volt, and readings increase at this setup to 9.0 mv/v at  $n=4$ . As this anomaly is associated with a low apparent resistivity anomaly, it is considered more significant than the higher readings obtained at the east end of the line. Survey lines should be run on either side of this anomaly.

The results over the east grid are presented on the remaining plates (4 to 9 inclusive). A broad zone of weak chargeability highs, on the order of from 6 to 10 millivolts per volt, trends across the eastern portion of the grid. It is generally spacially coincident with an apparent resistivity low, which may be indicative of fracturing or increased porosity of the underlying rock. Other weak chargeability highs are present, but are associated with high apparent resistivities and are considered to be of less interest. The "coincident zone" is located approximately as follows (as defined by the  $n=1$  and  $n=2$  separations):

- Line 2+00S; baseline to 250E; anomaly open to east
- Line 0+00 ; baseline to 200E; very low resistivity at 225E; anomaly open to east
- Line 2+00N; baseline to 200E; anomaly open to east
- Line 4+00N; not surveyed
- Line 6+00N; 200W to 50E; but high resistivity at 75W
- Line 8+00N; 200W to 100W; high chargeabilities at  $n=3$  and  $n=4$  associated with high resistivity
- Line 10=00N; 350W to 100W; anomaly open to east

This zone is a very weak geophysical anomaly. However, geological information indicates that little or no pyrite mineralization is present, whereas chalcocite has been identified in trenches just west of the baseline on line 0+00. Further work to determine the source of this anomaly is therefore warranted.

CONCLUSIONS

Portions of the THALIA mineral claims were surveyed with time domain IP in the summer of 1978. One line was surveyed on the "west grid", and six lines were surveyed on the "east grid".

A weak anomaly was detected on the line surveyed on the west grid. Response was strongest at the further separations, and further IP work is required to determine the extent of this anomaly.

A broad zone of coincident, weakly anomalous chargeability response and low apparent resistivities, extends along the eastern portion of the east grid.

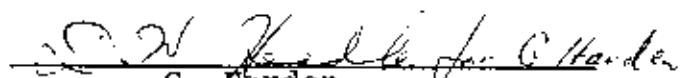

Subject to a more detailed geological and geochemical appraisal of the property, further work is recommended to determine the source of these anomalies.

APPENDIX III

C E R T I F I C A T I O N

I, Alan Scott, of 4013 West 14th Avenue, in the City of Vancouver, in the Province of British Columbia, do hereby certify that:

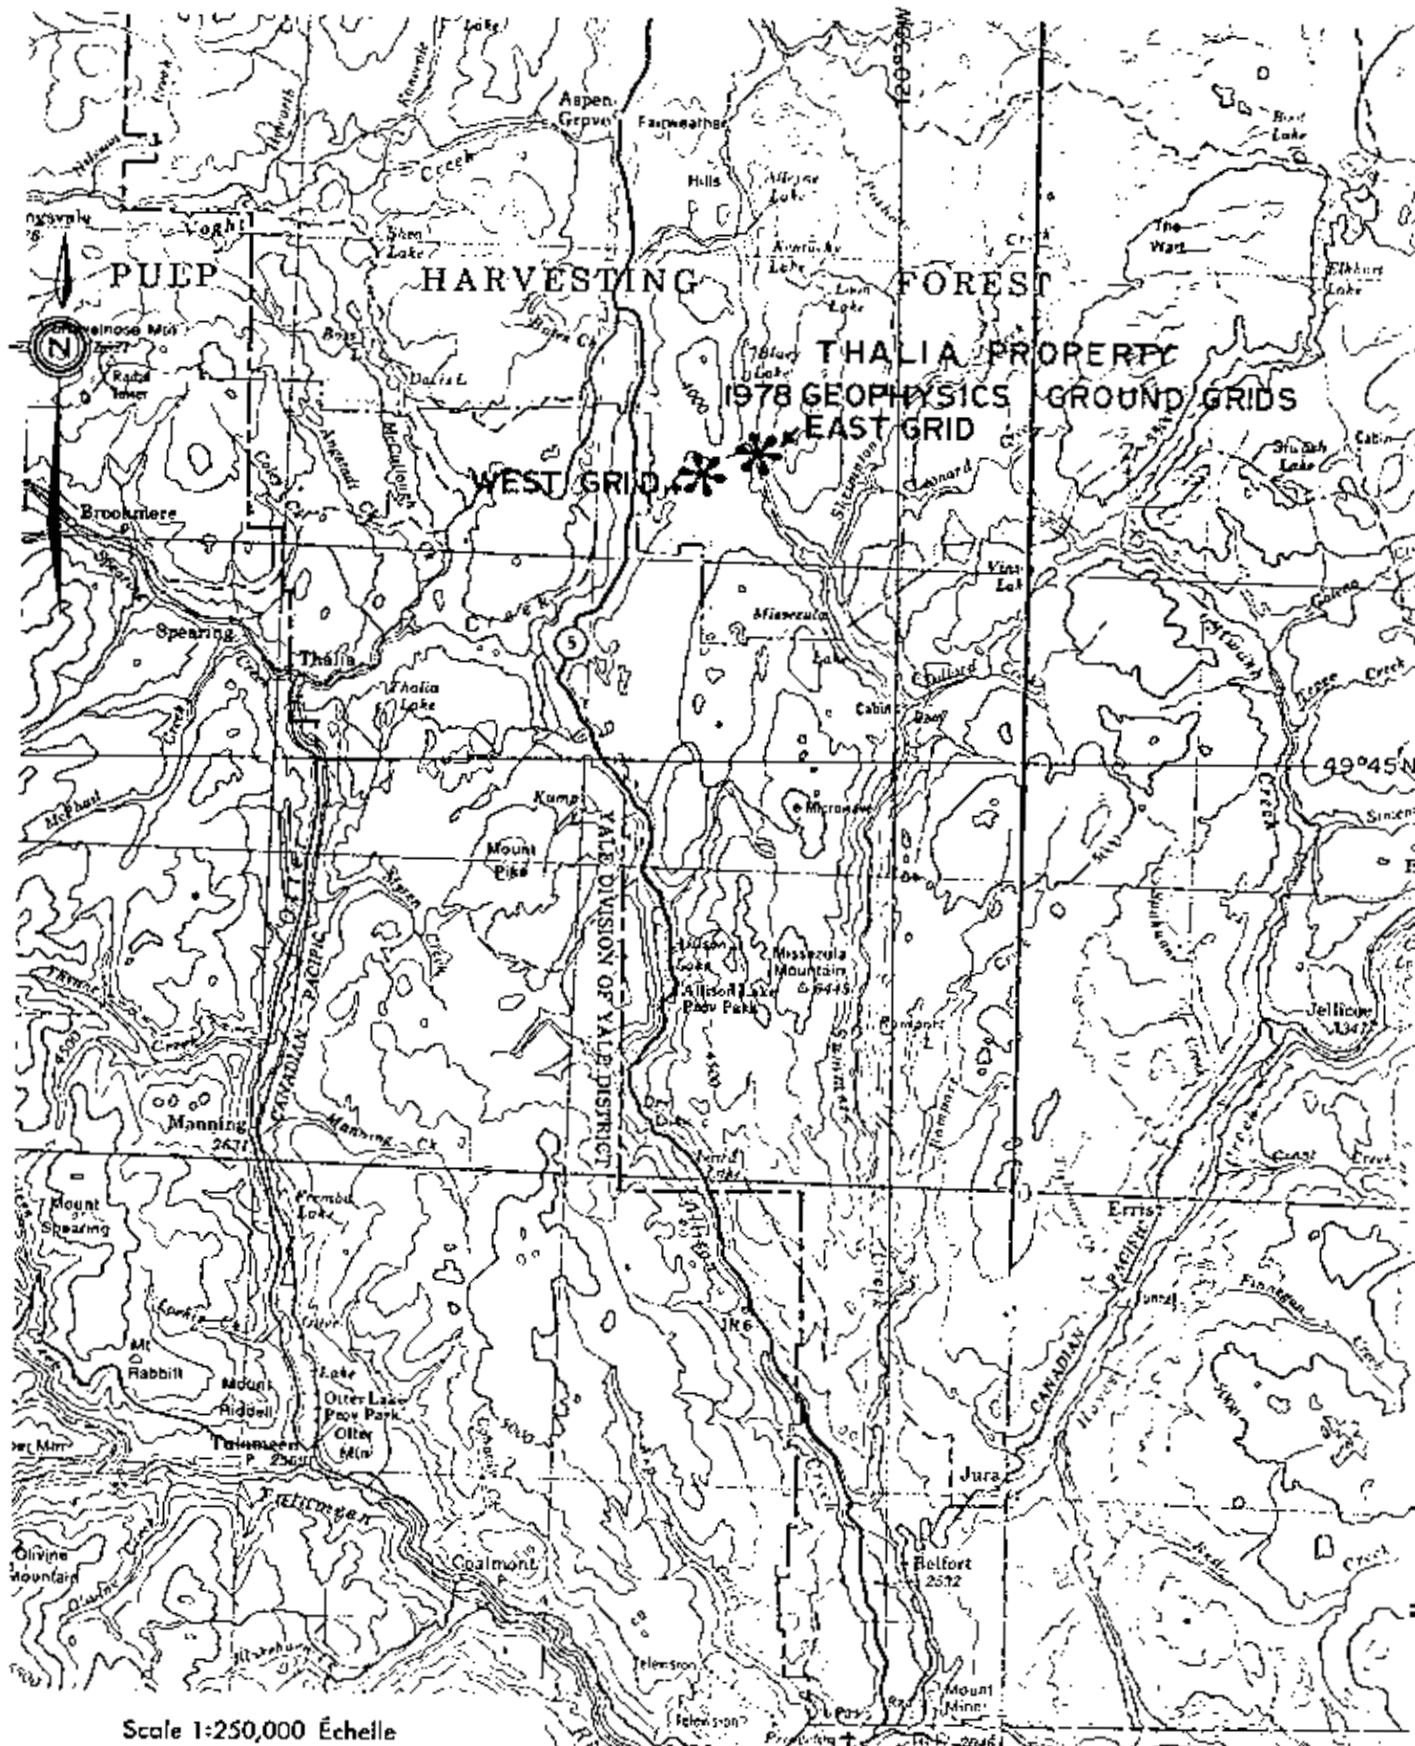

1. I graduated from the University of British Columbia in 1970 with a B.Sc. in Geophysics.
2. I am a member of the Association of Professional Engineers of the Province of Saskatchewan, the Society of Exploration Geophysicists of America, and the British Columbia Geophysical Society.
3. I have been practising my profession for the past nine years.
