INTRODUCTION

The DOBBIN property is located some 27 kilometers north-west of Kelowna, as indicated on the accompanying location map, plate 127-78-1. The location of the survey lines relative to the claims is shown on plate 127-78-2.

During the period August 20-29, 1978, a Cominco geophysical crew completed some 13.5 line kilometers of multi separation induced polarization survey on the property. The survey was conducted on two separate grids, namely the "Cu Grid" and the "Mo Grid".

This report describes the induced polarization survey, presents the data and discusses the results.

LOCATION AND ACCESS

The claims surround Tadpole Lake, at the headwaters of North Lambly Creek. Approximate geographic coordinates are 50°01'N latitude by 119°46'W longitude.

A good system of logging roads give access to the property, from highway 97 on the west side of Okanagan Lake. It is about a 45 minute drive from Kelowna.

GEOLOGY

The DOBBIN property consists of two distinct geological targets, a porphyry Mo target near Tadpole Lake in the north ("Mo Grid"), and an alkaline porphyry Cu target to the south ("Cu Grid"). The geology has been described in a report submitted for assessment purposes by Osatenko, May 10, 1978.

INDUCED POLARIZATION SURVEY

G. J. Niemeyer, geophysical technician, was the party chief/receiver operator on the survey.

A Scintrex IPR-8 receiver, in combination with a Huntex 7.5 kw motor generator/transmitter were used on the survey. This equipment operates in the time domain, employing a 2 second current on/2 second current off alternating square wave. The chargeability (IP) values plotted are the M232 values, and the units are millivolts/volt. To convert to the more common millisecond value (such as would be obtained with the older model IPR-7), the numbers should be multiplied by 0.7, for a "typical" decay curve. For a more detailed discussion of this instrument, the reader is referred to the Scintrex manual for the IPR-8.

The pole-dipole electrode array was used on both the Cu and Mo grid surveys, with an "a" spacing of 50 meters and "n" separation of 1, 2, 3, and 4. The current electrode was kept to the west of the potential dipole.

The apparent resistivity data is given in units of ohm-meters. It was calculated from the relation:

$$\text{apparent resistivity} = (V/I) \cdot K$$

where V is the voltage across the potential measuring dipole due to a current I, and K is a constant dependant upon the "a" spacing and "n" separation.

DESCRIPTION OF RESULTS

The induced polarization (chargeability) and apparent resistivity data is presented in standard pseudo section format on accompanying plates 127-78-3 to 5 for the "Cu Grid", and on plates 127-78-6 to 11 for the "Mo Grid". This is a schematic form of data presentation, and no geometrical or depth to target information is implied by it.

Cu Grid:

Lines 8+00S, 4+00S and 6+00N were surveyed on the Cu Grid. Anomalous responses were detected on all three survey lines, as discussed below:

Line 8+00S: - A strong chargeability high lies between 350W-550W. It peaks at 65 millivolts per

volt at n=1, and is coincident with an apparent resistivity low. Chargeability values are generally high from 100W to the end of the survey line at 800W. A moderate chargeability high lies between 550E to 650E.

Line 4+00S: - Chargeability values are generally high from 250W to the end of the survey line at 1100W. Strongest response at n=1 was between 350W to 450W and from 1050W to 1100W (end of line). A moderate chargeability high lies between 350E to 450E.

Line 6+00N: - Chargeability values are generally high from 50W to end of survey line at 700W. Strongest n=1 response in this zone is between 500W to 600W, but is associated with an apparent resistivity high.

A moderate to strong chargeability high lies between 550E to the end of the survey line at 750E. It is associated with an apparent resistivity low.

This survey served to confirm and relocate, anomalous chargeability highs coincident with pyrite/chalcopyrite mineralization. (The grid had been surveyed more completely on behalf of Atlas Exploration in 1969).

Mo Grid:

Lines 4+00N to 14+00N were surveyed at a 200 meter line interval over the Mo Grid (plates 127-78-6 to 11).

A strong chargeability high extends along the western portion of the Mo survey grid, and was detected on lines 4+00N to 12+00N. It is likely that line 14+00N did not extend far enough to detect the zone. The strongest response was on line 10+00N, where a n=1 value of 86.0 millivolts/volt plots at 875W. The greater than 60 mv/v zone on this line, extends from 550W to the end of the line at 1000W.

Outcroppings of sediments (argillites) containing up to 4% visible pyrite are coincident with this high charge-

ability area. The eastern edge of the high response area corresponds to the geologically mapped contact of the argillites to a granodiorite and/or quartz monzonite intrusive.

A moderate to strong chargeability high was detected on the eastern side of the Mo grid on lines 10+00N and 12+00N. It extends from 800E to the end of the survey line at 900E on line 10+00N; and from 750E to the end of the survey line at 1100E on line 12+00N. The strongest response was on line 12+00N. A coincident outcrop of argillites suggests this anomaly is mapping the eastern contact of the intrusive to sediments.

The central portion of the Mo Grid is characterized by low chargeability response. As only a very weak response could be expected at the low volume percent of molybdenite that would be of economic interest, the Mo potential of this central zone is indeterminate from the IP results alone. Weak local highs, such as on line 12+00N around 200E, could represent the response to weak concentrations of pyrite and/or molybdenite. More detailed correlation of these results to geological and geochemical information may indicate if further work is warranted.

CONCLUSIONS

Portions of the DOBBIN property were surveyed with time domain IP in the summer of 1978. Work was done on two separate grids, namely the "Cu Grid", an alkaline porphyry Cu prospect; and the "Mo Grid", a porphyry Mo target.

Only 3 widely spaced lines were surveyed on the Cu Grid, and strong chargeability highs were detected on all three lines. These highs were coincident with showings of pyrite/chalcopyrite mineralization, and served to confirm and relocate the results of a previous (1969) IP survey.

Work on the Mo Grid showed that an extensive zone of strong chargeability response lies on the western portion of the grid. A second chargeability high response

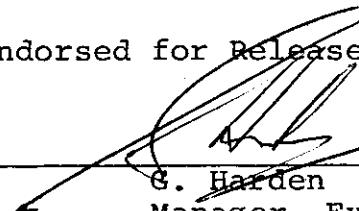

area was detected on two lines on the eastern side of the grid. These IP highs are believed to be caused by disseminated pyrite in sediments. The central portion of the grid has generally low chargeability values.
