INTRODUCTION

The CK claims are located some 50 road kilometers north east of Clearwater, B.C. Plate 132-78-1 shows the general location of the property, and plate 132-78-2 shows the lines surveyed in relation to the claims.

During the 1978 field season, a total of 38.3 line kilometers of multi separation induced polarization survey, 39.3 line kilometers of total field magnetics survey, and 21.8 line kilometers of VLF electromagnetics survey were completed over portions of the CK claims. Although the work forms one continuous grid of data, it was conducted as three separate surveys. All the work was done by Cominco geophysical crews, except for the third IP survey which was done under contract by Peter E. Walcott & Associates Ltd.

The data from the first two surveys was submitted for assessment credits in June and October of 1978. This report gives the results of the third survey, which consisted of 17.3 line kilometers of magnetics survey and 17.4 line kilometers of IP survey.

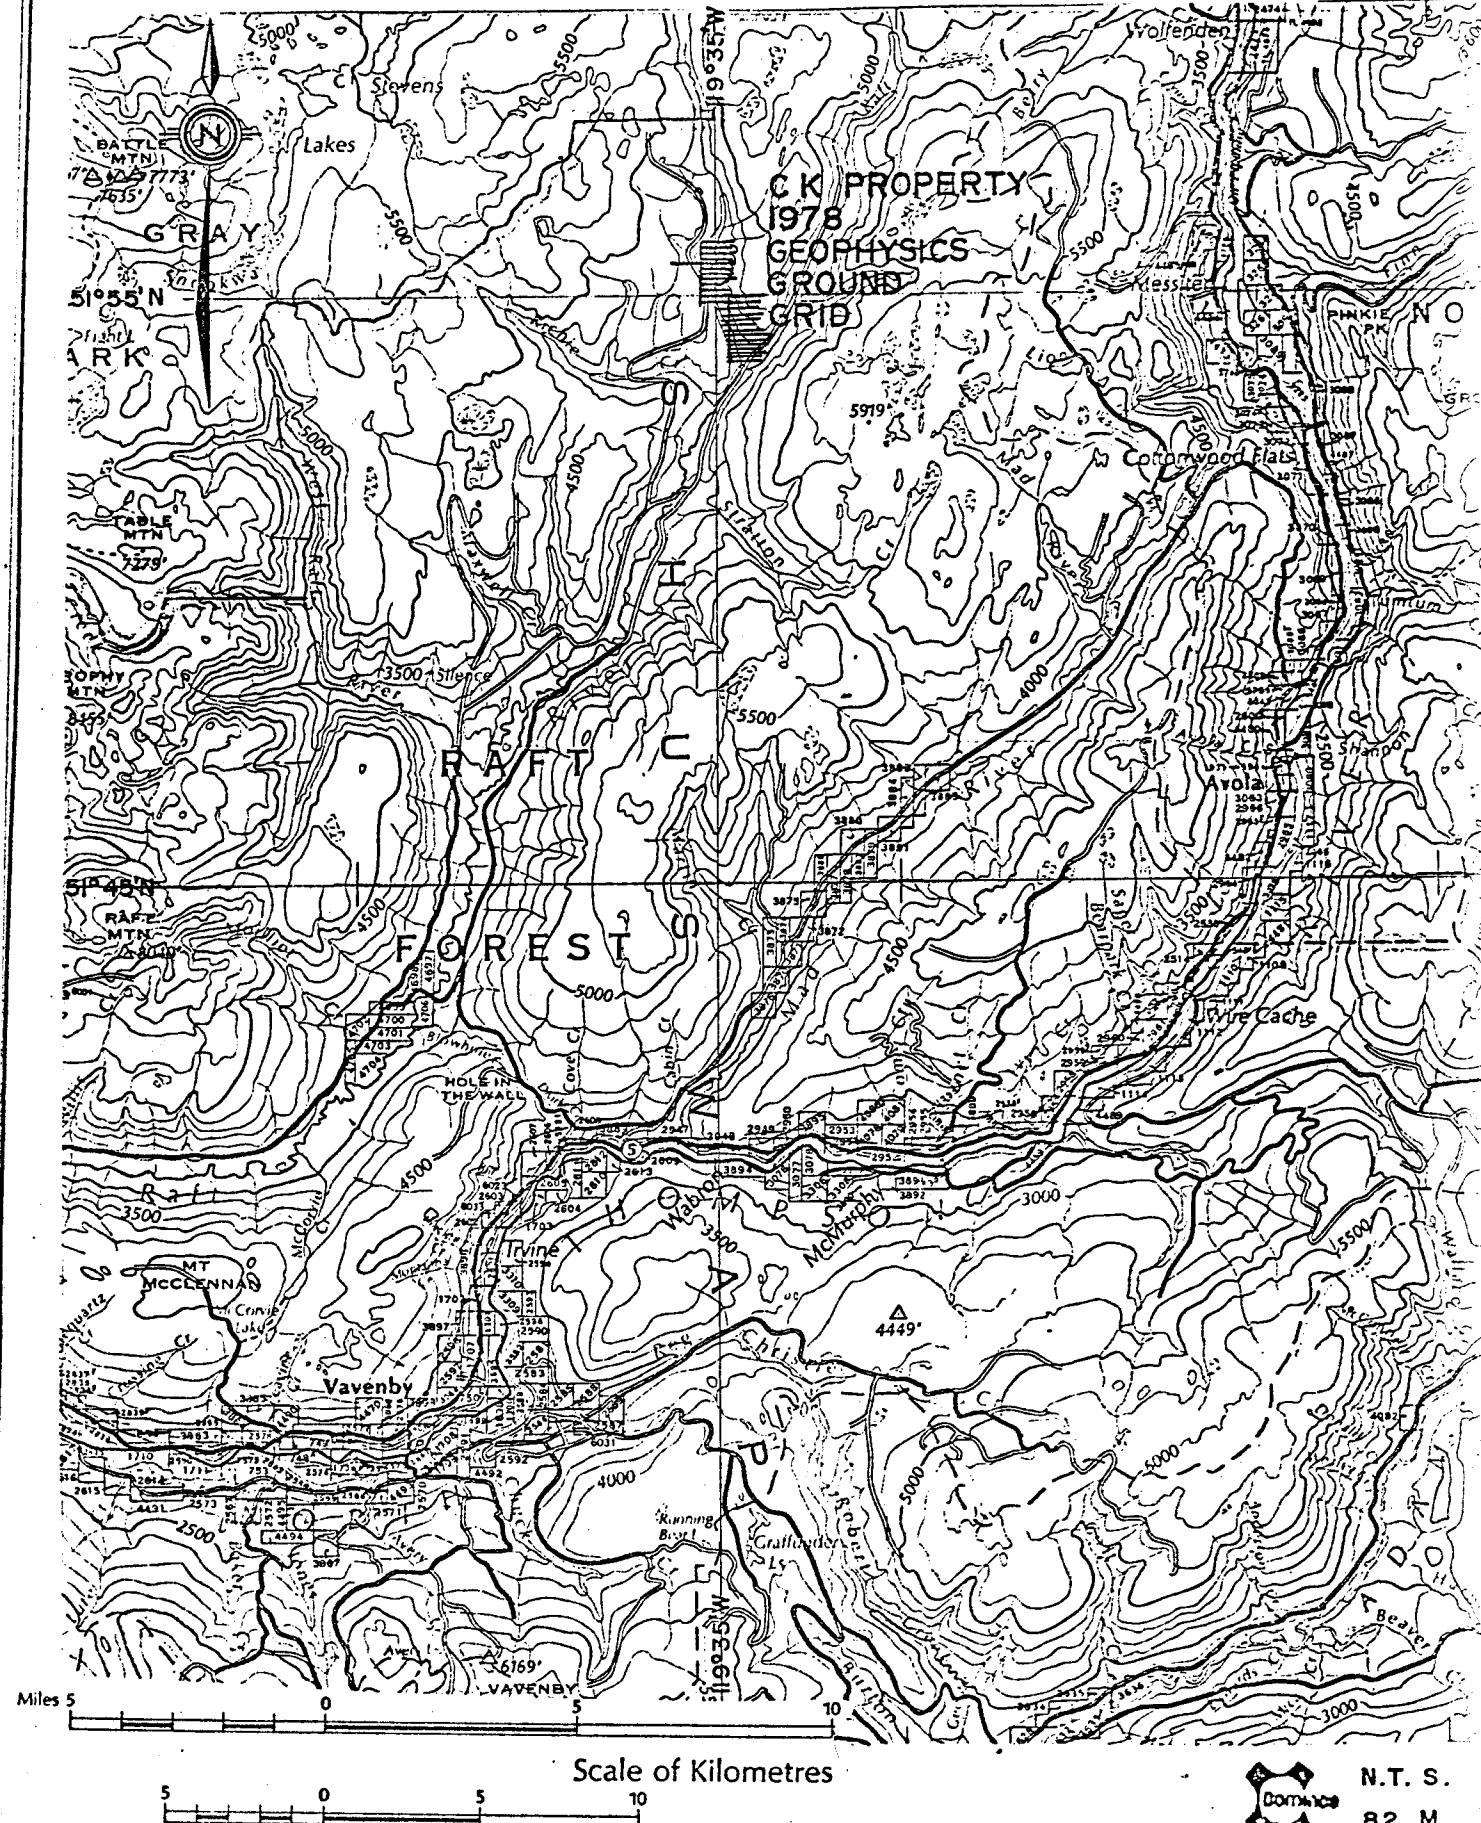

LOCATION AND ACCESS

Access to the CK claims can be gained by turning north off highway number 5 at Clearwater onto a well maintained logging road, which follows the Raft River valley. The 1978 geophysical survey grids straddle McClosky Creek, which drains into the Raft River some 50 road kilometers north of Clearwater. (Location map on following page).

GEOLOGY

The CK property is underlain by highly metamorphosed sediments of the Shuswap Complex. Dominant rock types are biotite gneiss and pegmatite along with amphibolite, calc silicate, marble, and lamprophyre and diabase dykes.

The geology and geochemistry of the property has been described in detail elsewhere (Murrell 1979).

GEOPHYSICAL SURVEYS

Magnetics Survey

Scintrex MP-2 proton precession magnetometers were used for the magnetics surveys. The instrument reads the earth's total magnetic field to the nearest gamma. The data was corrected for diurnal variation using the base station and sub base station looping method, and tie ins between surveys was accomplished by repeating sections of adjacent lines.

Readings were normally taken at 25 meter intervals on cross lines 100 meters apart. The data is presented in contour plan form on plate 132-78-3, which includes the data obtained from the two previous 1978 surveys.

Induced Polarization Survey

The IP survey was conducted under contract by Peter E. Walcott & Associates. Data from this survey is plotted on pseudo section plates 132-78-30 to 43 inclusive.

A Crone N-IV receiver and Huntac 7.5 KW motor generator/transmitter were used for the Walcott survey. This is a time domain system and the same 2 second on/off charging cycle was used for this survey as was used on earlier surveys conducted by Cominco with a Scintrex IPR-8 receiver. However, the Crone receiver gives chargeability values in a different fashion to the Scintrex IPR-8. The Crone unit reads out the ratio of secondary to primary voltage integrated over a period of time. Units are therefore given as millivolt seconds per volt, or more commonly stated simply as milliseconds. A conversion factor has been applied to all the Walcott data to make it conform to the values that would have been obtained for an IPR-8. The factor was calculated as the average ratio of Crone N-IV to Scintrex IPR-8 for the 23 overlapped stations on lines 0 to 5N. The value obtained was 1.47.

The pole-dipole electrode array was used on the surveys, with an "a" spacing of 50 meters and "n" separations

of 1,2,3, and 4. Some detail coverage was also obtained at an "a" spacing of 25 meters. In all cases, the current electrode was kept to the west of the potential dipole.

The apparent resistivity data is given in units of ohm meters. The values were calculated from the relation:

$$\text{apparent resistivity} = (V/I) \cdot K$$

where V is the voltage across the potential measuring dipole due to a transmitted current I, and K is a geometric factor dependent upon the "a" spacing and "n" separation.

DISCUSSION OF SURVEY RESULTS

Magnetics

The total field magnetics data is plotted and contoured in plan form, on accompanying plate 132-78-3.

The dominant pattern is of a series of discontinuous, elongated, moderate amplitude, magnetic highs trending northwest to southeast across the property. These relatively large scale features presumably represent the response of stratigraphic units that are relatively magnetic. Amphibolite and some of the biotite gneisses are likely candidates for these highs; and pegmatites and marbles in areas of low (background) magnetic field strength.

In addition to these large scale, weakly magnetic features, there are several localized strongly magnetic highs. These features may be caused by either pyrrhotite mineralization, or magnetite associated with lamprophyre or diabase dykes.

Induced Polarization

The induced polarization (chargeability) and apparent resistivity results are presented in pseudo section format on the accompanying plates 132-78-30 to 35 for lines 1700S to 1200S, and on plates 36 to 43 for lines 100S

to 500N.

The strongest response on the southern survey area was on line 1200S, between stations 1900E and 2150E. The anomaly was detailed at a 25 meter electrode separation, and showed two distinct anomalies, one at 1912E and a wider anomalous zone from 2000E to 2075E. Both anomalies have coincident low apparent resistivities.

The strongest response on the northern area was on line 100N between station 800E and 950E. Again detailing at a 25 meter electrode separation gives distinct anomalies with one zone centered at 820E and the other at 900E. The anomaly at 825E has coincident low apparent resistivity.

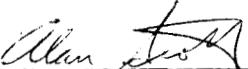

CONCLUSION

Magnetics and multiseparation IP surveys were conducted over portions of the CK claims in the fall of 1978, to further define the extent of anomalies detected on two earlier surveys done in the summer of 1978. Results of those surveys were reported previously (June and October 1978).

Several high chargeability zone were detected on the present survey, with the strongest responses on lines 1200S and 100N, as described in the previous section.

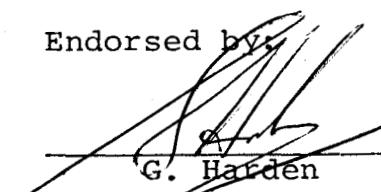

Drill testing to determine the source has been recommended. Depending on the results of such testing, other lower amplitude anomalies along strike to these could also warrant testing.

Respectfully submitted,

Alan Scott
Geophysicist
