I INTRODUCTION:

1. Location and Access

The Easy 1-6 claims are situated immediately to the north and east of Likely, B.C. in Cariboo M.D. (Fig 1). The area under investigation (Grid 1) described herein occupies approximately the southwest quarter of Easy 1 claim (Fig 2). Two main gravelled roads (to Keithly Creek and to Spanish Lake) cross the grid. These together with a number of bush roads provide ready access to the property.

2. History and Ownership

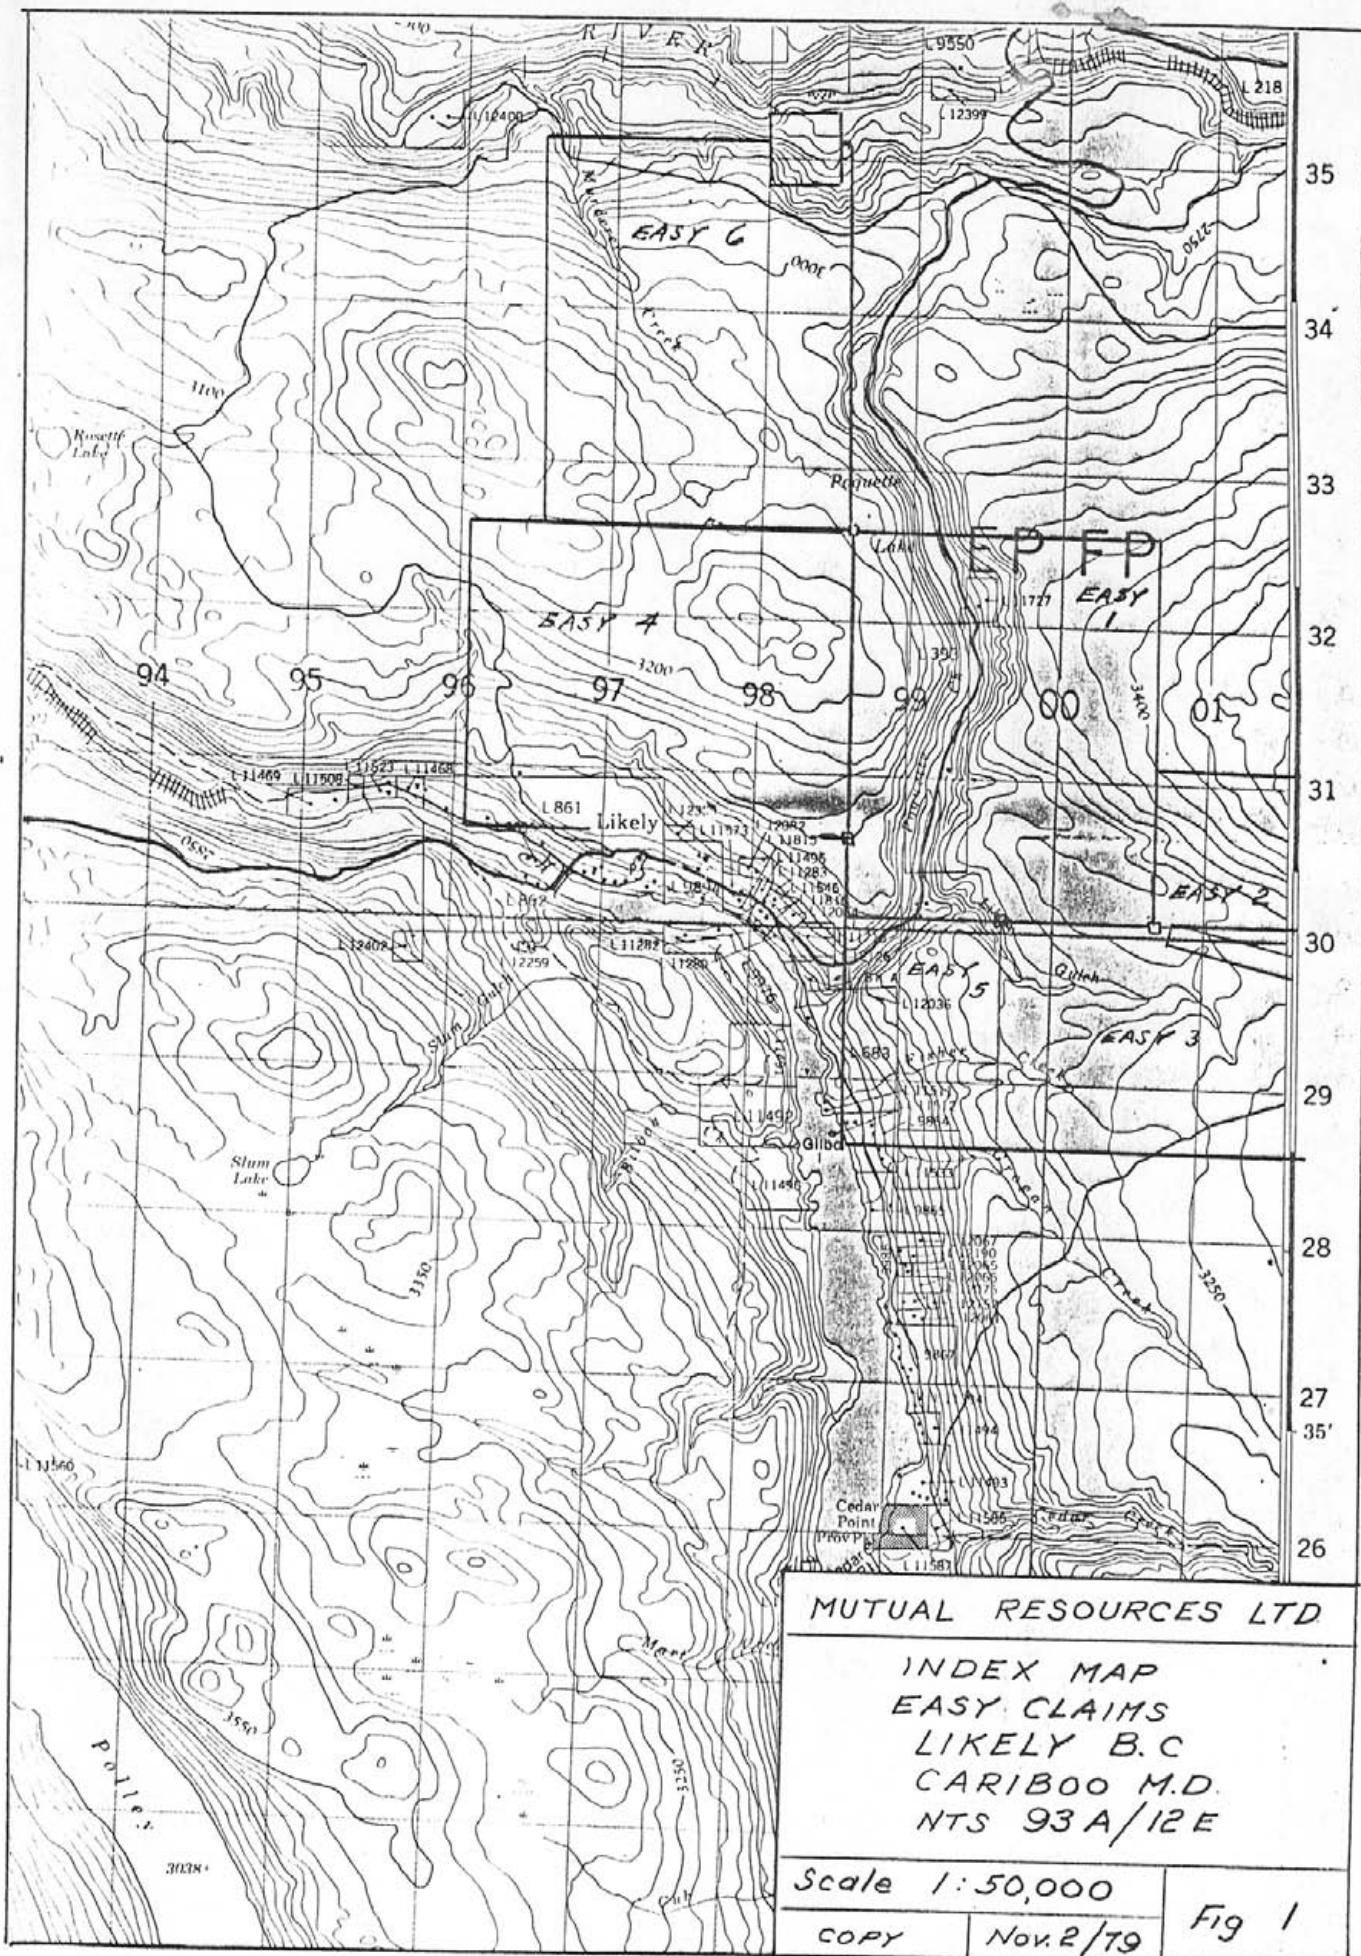

A small creek, which enters Poquette Creek from the east at a point about 1 Kilometre south of Poquette Lake, together with most of the creeks in the area, was worked for placer gold in past years. At the point where the creek emerges from a gully to enter the Poquette valley, early prospectors noted that a system of quartz stringers occurred in bedrock at, and just above creek level. Subsequently, these stringers were investigated by adit (and winze?) now concealed under talus; and later by blasting and cat trenching to open up the showings. Results of this early work are not known to the writer. Mention of quartz gold in Poquette Creek is made in the literature pertaining to activity early in the century.

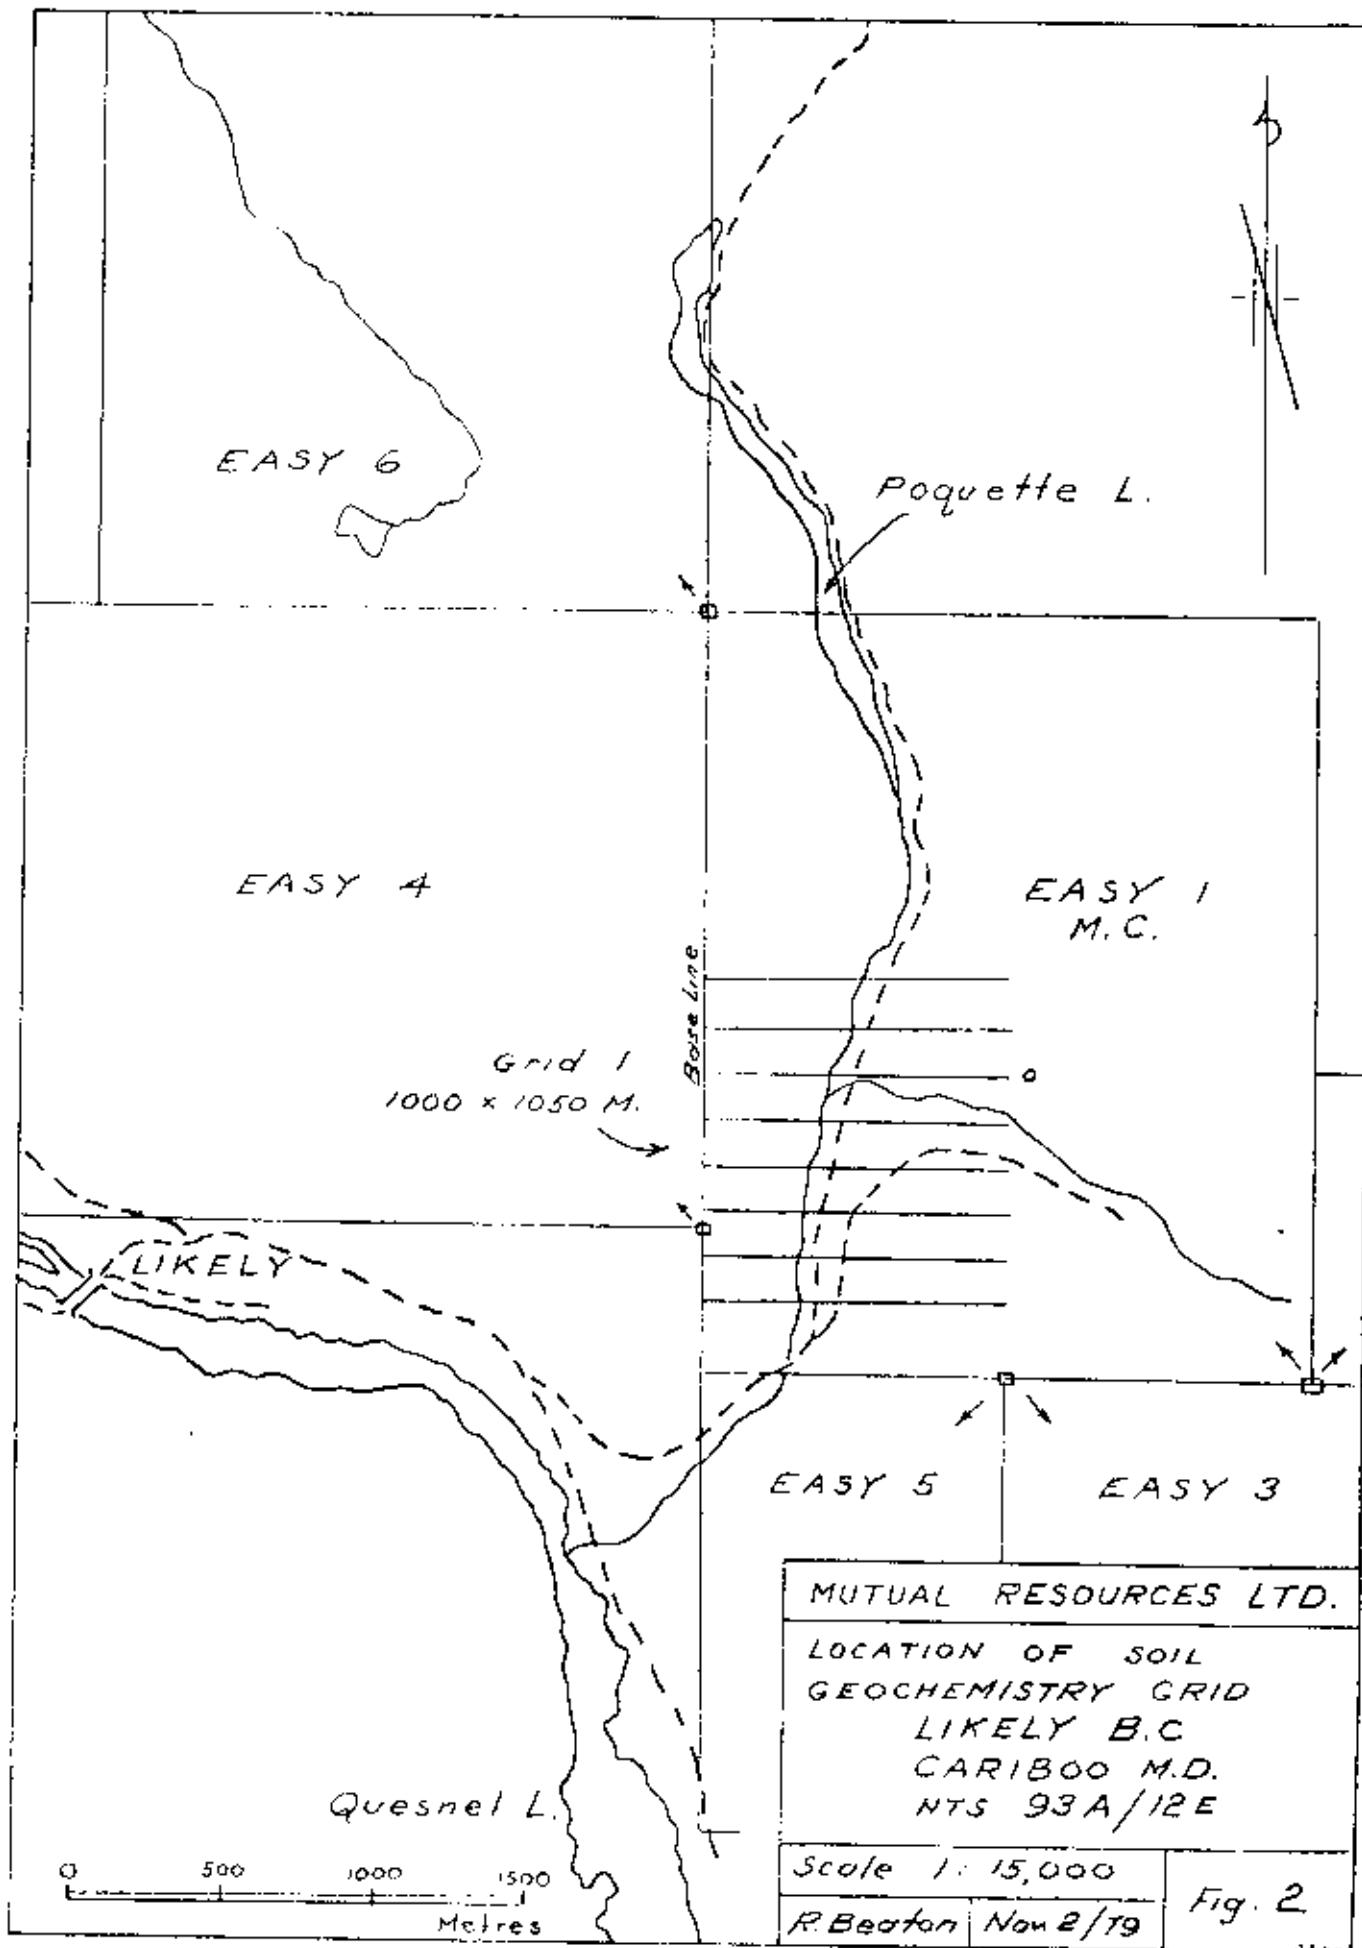

In 1978 prospector R. Mickle, staked ground including the old quartz showings and prospected for additional occurrences in the general vicinity. By agreement dated December 29, 1978, Silver Standard Mines Ltd., optioned Mickles holdings (Easy 1-3, 5, 6). An additional claim (Easy 4) was staked and recorded for Silver Standard in that same month.

During May 1979 soil geochemical work was done on Easy 6 and on Easy 1 (this report); and during October 1979 a 4-hole drilling program was conducted also on Easy 1. This work was performed by Mutual Resources Ltd., which subsequently had transferred to it the rights from Silver Standard.

3. Summary of Work Performed

During May 1979, 7 lines for a total of 7000 metres (Grid 1) were cut on Easy 1 M.C. with station at 25 metres and line separation at 150 metres. This work followed the running of a reconnaissance soil line (line 0) of 1000 metres to determine response of six metallic elements.

A total of 991 analytic determinations were made by Chemex Labs Ltd., as follows:

	<u>Soil Geochemistry</u>	<u>Rock Geochemistry</u>	<u>Rock Assay</u>
Au	268	17	5
Ag	268	17	5
As	268	17	
Cu	35	7	
Pb	35	7	
Hg	35	7	
	<u>909</u>	<u>72</u>	<u>10</u> TOTAL 991

II PURPOSE:

The purpose of the soil-grid program was to determine, in an area where outcrop was largely limited to creek banks and road cuts, if systematic sampling might serve to provide targets for subsequent investigation in an area known to include quartz veining carrying low values in gold silver together with weak but visible amounts of arsenopyrite, galena, and chalcopyrite.

The initial reconnaissance line (Fig 6) showed that geochemical response was excellent where glacial cover was thin or lacking; but poor where cover was thick or consisting of clayey material. Since depth and type of cover were unpredictable; and since alternative exploratory methods would involve much greater cost, it was decided to expand the initial test line to a limited grid involving the three elements (Au, Ag, As).

III PROCEDURE:

The original or reconnaissance line was run by compass, hip chain, and altimeter; using flagging for markers. The subsequent grid lines were cut by chain saw, blazed, and marked by station pickets at 25-metre intervals.

Soil samples were taken from the B1 horizon is possible normally at depths of 15 to 30 cms; but from clean glacial silt below the organic level where the B1 horizon was not present. Creek slopes and sandy or porous soil provided excellent sample material. Samples were collected by spade, mattock, and in places soil auger. Roots and coarser material were rejected before placing finer material in suitably marked water-resistant kraft soil envelopes. Samples were shipped directly in damp condition to Chemex Labs Ltd., of North Vancouver for analysis. Rock geochem samples were taken as chips from the few grid-line outcrops, placed in suitably marked kraft envelopes, and shipped directly to Chemex.

IV RESULTS:

Results from the multi-element sampling of the reconnaissance line (line 0) showed moderate to strong response where cover was thin or lacking and weak to negligible elsewhere. Where response was good the following were determined by inspection:

Response	ppb Au	ppm Ag	ppm As	ppm Cu	ppm Pb	ppb Hg
Background	<20	<0.2	<50	<35	<4	<30
Threshold	20-40	0.2-0.4	50-100	35-70	4-8	30-60
Anomalous	>40	>0.4	>100	>70	>8	>60
Strongly Anomalous	>500	>3	>500	>400	--	--

Both arsenic and copper appeared to offer best promise as indicators hence the former together with gold and silver were selected for soil analysis on the remainder of the grid.

Results of the three-element analysis (Au, Ag, As) when plotted (Figs 3,4,5 in pocket) showed two areas that provided coincident anomalous values. Others, including a large area in the southwest part of the grid, are attributed to proximity to intrusive bedrock and/or solution migration in permeable drift. The two of interest are confined to the valley slopes of Poquette Creek. That on the east slope provided better than 300 ppb Au on lines 0 and 150 S, better than 300 ppm As on lines 0 and 300 S, and better than 1 ppm Ag on line 0. It also included the quartz veining mentioned in History and Ownership on page two. That on the west slope directly across Poquette Creek from the former provided better than 300 ppb on lines 0 and 150 S, better than 300 ppm on lines 150 N to 450 S, and better than 1 ppm Ag on line 0 and 150 S. This westerly anomaly also included altered quartz diorite (not shown on Geology Map 93A Quesnel Lake, Campbell, 1978) which carried minor galena and chalcopyrite in narrow stringers in the vicinity of station 4 west, Line 0.

V INTERPRETATION:

Since strongest soil value returns came from areas where glacial cover is thin, lacking, or permeable it follows that any geochemical program can only provide results which are not likely to be equally representative of underlying bedrock or which through migration of ions in ground or thermal waters may not represent underlying bedrock at all.

Evidence here, from elsewhere on the Easy claims, and from later drilling suggests that gold is associated with narrow widely-spaced quartz stringers in Campbells northwesterly-trending Tr Ja unit (fine grained basaltic tuffs, breccias

and argillite). Invariably these stringers favor pale grey tuffaceous or bleached horizons. The stringers in Poquette valley, in addition, include minor amounts of galena, chalcopyrite and arsenopyrite which may be related to contacts of the intrusive diorite - quartz diorite exposed on the west slope. Secondary arsenopyrite and pervasive pyrite may also be seen in the altered intrusive rock and occasionally in fresher intrusive diorite in the south westerly portion of the grid. Pyrite is persistent in the argillites and volcanic rocks throughout the claim area.

The rocks on both sides of Poquette valley are intensively shattered, goudgy, and invariably rusty from contained pyrite. It is obvious that they have been subjected to pronounced tectonism resulting from repeated movement associated with a postulated fault system along Poquette Creek and/or intrusive activity from a crystalline body flanking the west side of Poquette Creek. Thermal or ground waters again possibly resultant from faulting or intrusive activity may have been causative to bleaching alteration; and to introduction of secondary pyrite, arsenopyrite and calc-silicate veining in adjacent host rock.

The anomalous gold-in-soil values, since they are in most cases associated with coincident arsenopyrite and chalcopyrite suggest a common origin as outlined in the previous paragraph. Occasionally erratic very high Au in soil values have been found in sampling. These may reflect the presence of free (placer) gold; or more simply may have resulted from weathering of quartz stringers to provide occasional 'Kicks' which seldom repeat on resampling. Origin of such anomalous gold in soil is speculative.

VI CONCLUSIONS:

1. Anomalous gold, silver, arsenic, and copper in soil from geochemical grid I on Easy 1 M.C. are believed to have originated in part from mineralized quartz veining associated with a highly-altered phase of a diorite or quartz diorite body exposed on the west side of Poquette Creek.
2. Gold and silver in addition may result from chert and/or calc-silicate veining resultant from widespread movement of crustal water or hydro thermal solutions in a favourable Triassic - Jurassic volcano-sedimentary host (Campbell's Tr Ja Unit) which exhibits bleaching or alteration in consequence.
3. Erratic very high gold values may occur in occasional soil samples due to the presence of free gold on bedrock or in glacial sediment derived in part from gold-quartz veins or stream concentrations of unknown or speculative origin.

ITEMIZED COST STATEMENT
Grid I (Prorated Costs)

WAGES: May 12-17, 19-21

AUTHORS QUALIFICATIONS

I, R. H. Beaton, of the City of Vancouver in the Province of British Columbia certify that I am a Professional Engineer registered in the province of British Columbia, that I graduated from the University of British Columbia with a B.A.Sc in Geological Engineering in 1952, that I personally supervised and participated in the geochemical investigation on Easy 1 Mineral Claim, and that I was employed by and worked under direction of the officers of Mutual Resources Limited while so engaged.

Vancouver, British Columbia
November 30, 1979

Sample Preparation

Sils, silts, lake bottom sediments - Samples are sorted and dried at 50°C for 12 - 16 hours. Dried material is then screened to obtain the -80 mesh component of each sample. Coarse material is discarded unless other instructions are received. Other mesh sizes are available if required.

Rock chips or pieces of core designated as rock geochem samples are dried, crushed and then pulverized to -100 mesh in a ring grinder. The sample is homogenized and packaged.

Sample Analyses

ppm Copper & Lead:

A 1.0 gm portion of sample is digested in conc. perchloric-nitric acid (HClO_4 - HNO_3) for approx. 2 hours. The digested sample is cooled and made up to 25 mls with distilled water. The solution is mixed and solids are allowed to settle. Copper and lead are determined by atomic absorption techniques using background correction for lead.

ppb Mercury:

The sample is digested with nitric acid plus a small amount of hydrochloric acid. Following digestion the resulting clear solution is transferred to a reaction flask connected to a closed system absorption cell. Stannous sulfate is rapidly added to reduce mercury to its elemental state. The mercury is then flushed out of the reaction vessel into the absorption cell where it is measured by cold vapour atomic absorption methods with a Jarrell Ash Multi-Versatility Spectrophotometer. The absorbance of samples is compared with the absorbance of freshly-prepared mercury standard solutions carried through the same procedure. The detection limit of this method is 5 ppb.

GEOCHEM PROCEDURES

PPB Gold: 5 gm samples ashed @ 800°C for one hour, digested with aqua regia - twice to dryness - taken up in 25% HCl-, the gold then extracted as the bromide complex into MTBK and analyzed via A.A.

Detection limit = 10 PPB

PPM Arsenic: a 1.0 gram sample is digested with a mixture of perchloric and nitric acid to strong fumes of perchloric acid. The digested solution is diluted to volume and mixed. An aliquot of the digest is acidified, reduced with KI and mixed. A portion of the reduced solution is converted to arsine with NaBH₄ and the arsenic content determined using flameless atomic absorption.

Detection limit = 1 PPM

PPM Silver: a 1.0 gm portion of sample is digested in conc. perchloric-nitric acid (HClO₄ - HNO₃) for approx. 2 hours. The digested sample is cooled and made up to 25 mls with distilled water. The solution is mixed and solids are allowed to settle. Silver is determined by atomic absorption technique using background correction on analysis.

Detection limit = 0.1 PPM
