1. INTRODUCTION

This report presents data obtained from field investigations near Surprise Lake for the proposed Mini-Hydro Scheme which forms part of the overall program to bring Placer Development's Adanac Molybdenum Mine into operation. The field work associated with Klohn Leonoff's involvement consisted of a drilling program supervised by our company and a hammer refraction seismic survey conducted by Silvicast Enterprises Ltd.

The property consists of 37 placer leases which run from Surprise Lake to Atlin Lake, not all of the claims are continuous due to previously staked placer leases on the area. A listing is as follows:

<u>Claim Name</u>	<u>Tag #</u>
PL 2530 - 2551	P 6760 - 6781
PL 2552	P 7709
PL 2553	P 7713
PL 2554 - 2767	P 7715 - 7728

The claims are shown on Drawing No. B-2685-205

The leases extend from Surprise Lake west along Pine Creek to its mouth on Atlin Lake about three kilometres south of Atlin, B.C. The eastern end of the leases have an access along Surprise Lake Road east from Atlin. The western end of the leases have an access from Warm Bay Road running south from Atlin.

Vegetation along Pine Creek Valley varies from low shrubs to scrub timber along the flood deposits to coniferous growth along the valley walls.

2. FIELD INVESTIGATIONS

2.1 Drilling Program

Five holes were drilled to determine the nature of the overburden and in two holes, the bedrock quality. The drill hole locations are shown on Drawing B-2685-204. Qualifications of Klohn Leonoff personnel are documented in Appendix 1.

The Contractor, Midnight Sun Drilling, elected to use a CME 750 rig for the drilling program, which began on August 7, 1980. Eight-inch diameter hollow stem augers were used above bedrock, except where the density or coarseness of the soil required the use of tricone bits and drilling mud. NQ size diamond bits were used to core the bedrock in Drill Holes #3 and #5. The core has been stored at the Adanac Ruby Creek Site.

2.2 Hammer Refraction Seismic Survey

The hammer refraction seismic survey was conducted by Mr. W.W. Moore, P. Eng. of Silvicast Enterprises Ltd. The survey description and the results are included in Appendix II. The location of the surveys are shown on Drawing B-2685-204.

3. RESULTS

The overburden samples recovered showed that the soils can be generally classified as silts and sand and gravels. Most of the overburden is in a dense condition as indicated by high values of the Standard Penetration test blow counts. Bedrock was encountered in Drill Hole #3 at a depth of 13 feet. The 21 feet of core that was recovered was siltstone in a highly fractured condition (i.e.,

RQD = 0). In Drill Hole #5, bedrock was encountered at a depth of 49 feet and cored for 21 feet. Weathered serpentine was recovered with a high density of healed fractures. The total core recovery and RQD percentages are shown on the drill hole logs, which are listed in Appendix III. Water levels were estimated in mud filled holes after standing over night. These are shown on the drill hole logs. Photographs of representative samples and drill hole locations are documented in Appendix IV.

4.

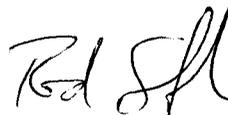

EXPENSES

An itemized list of expenses incurred on the drilling program is shown in Appendix V.

APPENDIX I

Personnel Qualifications

APPENDIX I  
PERSONNEL QUALIFICATIONS

PERI E. MEHLING, E.I.T

- B.A.Sc., Civil Engineering, University of British Columbia, 1979.

Ms. Mehling has been involved in various aspects of geotechnical investigations, including drilling supervision, laboratory work and report preparation.

H. RODNEY SMITH, P.Eng.

- B.A.Sc., Engineering Geology, University of British Columbia, 1971.
- M.A.Sc., Mineral Engineering, University of British Columbia, 1975.
- M.Eng., Geological Engineering, University of California, Berkeley, 1980.

Mr. Smith has been involved in geotechnical investigation programs for slopes, foundations, tunnels and embankments. His responsibility has included field direction of investigations, slope design and report preparation.

Attention: Dr. V. Garga, P. Eng.

Dear Dr. Garga:

As requested by Mr. R. Smith of your organization, the following is a brief summary of the refraction hammer seismic survey conducted by us, for Placer Development Limited, at Atlin, B.C., during the month of August of this year.

Period of Survey: August 11 to 17, 1980.

Type of Survey: Two-man Hammer Refraction Seismic.

Equipment Used: Single channel, Model 1570-C Bison Signal Enhancement Seismograph, and 16-pound sledgehammer.

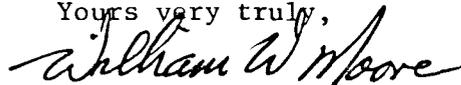

Location of Survey: On or adjacent to centre-line of proposed hydro canal, and power house sites between Surprise Lake and Atlin Lake, in the Spruce Creek drainage at Atlin, B.C.

Field Method: Under the direction of Mr. R. Smith and Mr. S. Porter of Klohn Leonoff, and at sites selected by them, 30 to 60 metre seismic lines were established on centre line, and transverse to centre line; using two geophones to provide reverse profile data.

Interpretation: The standard interpretation method, consisting of mathematical relationships between the critical distance and velocity ratios, was employed. Interpretation was performed to the best of my ability and experience. Nevertheless, inherent and well-known limitations of this system, e.g., side refraction, and overlapping velocities of various materials (see Caterpillar rippability charts) must be appreciated. It was obvious from the results that velocities in glacial fill are generally substantially greater in the survey area than in Southern B.C., probably as a result of denser compaction during periods of glacial activity.

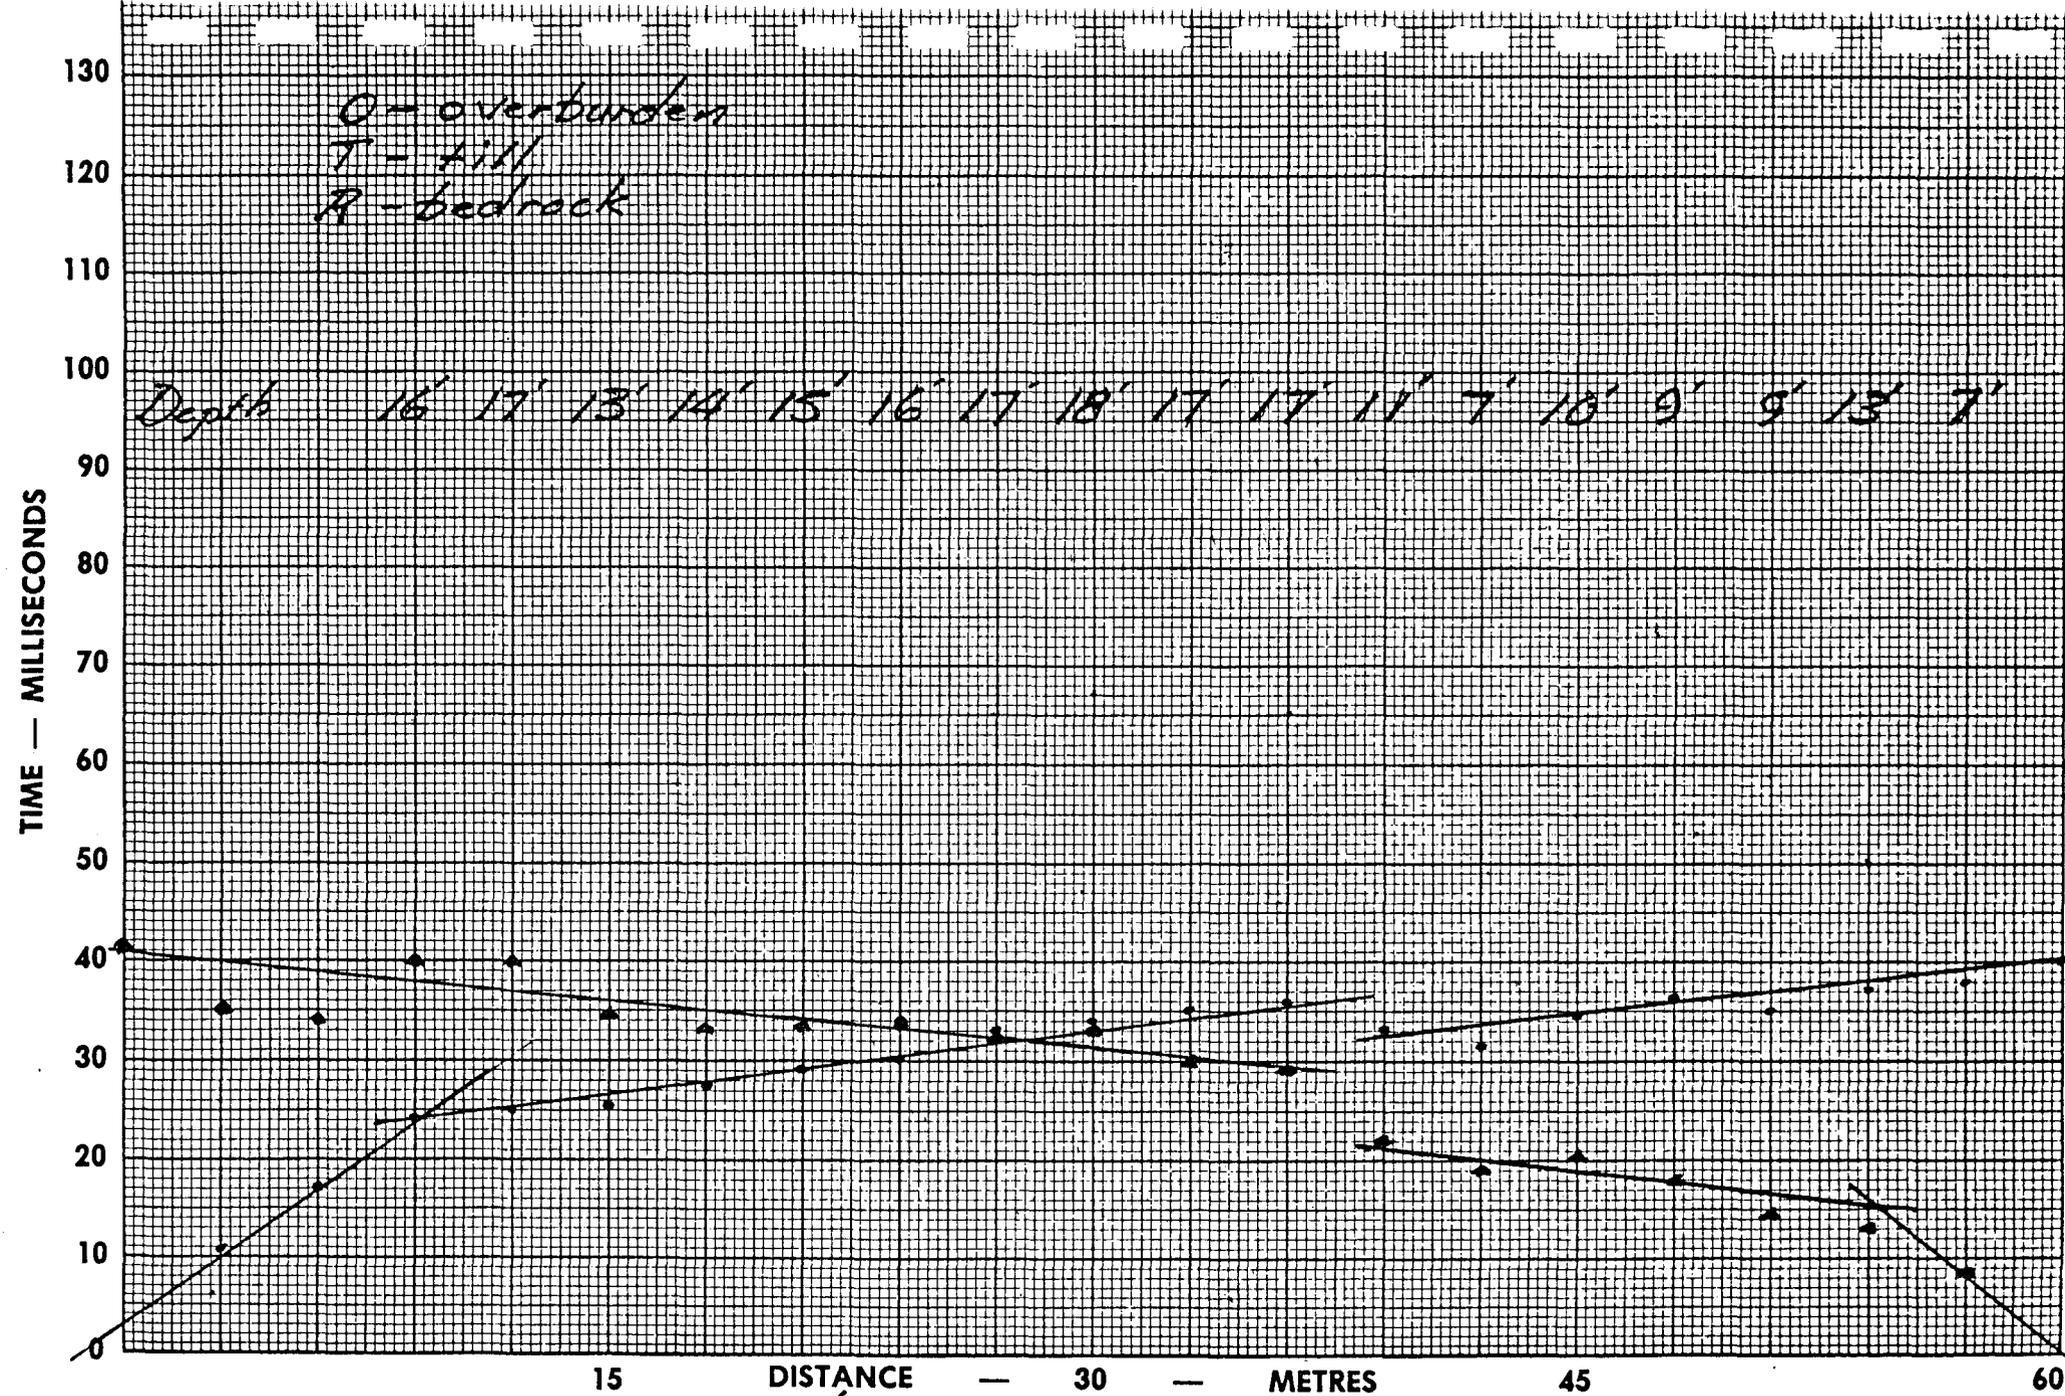

Trusting that the above information is satisfactory. We look forward to being of further service to your organization.

Yours very truly,

William W. Moore, M.F., P.Eng.  
President
