#### SUMMARY

A 782 line kilometre airborne electromagnetic/ magnetic survey was conducted on the Midway property which straddles the B.C./Yukon border approximately 90 kilometres west of Watson Lake, Y.T. At the time of the survey, the property consisted of 160 claims (Mid 1-160) in the Yukon and 39 claims (Way 1-25, Bull 1-3, Macc, Climax 1-11, Post 1) and one fractional claim (Bull 4 Fr.) in British Columbia.

The property is underlain by a sequence of clastic sedimentary rocks the lowest unit of which, a graphitic shale, hosts barite beds and exhalative chert horizons. A bedded massive sulphide horizon is located on the Bull 3 claim in a similar stratigraphic position.

Of numerous electromagnetic anomalies recorded by the survey the majority are caused by wide (or multiple), probably flat lying conductors and none can be readily attributed to a massive sulphide response.

A resistivity map prepared from the electromagnetic data shows that the area is moderately to highly conductive and that zones of very high conductivity correlate with the observed shale units.

Several small magnetic closures associated with conductors on the east side of the property suggest the presence of sulphides although known mineralization elsewhere is devoid of magnetic minerals.

#### INTRODUCTION

Results of a 782 line kilometre airborne electromagnetic and magnetic survey (Figure 1) flown on the Midway property are documented in this report. The survey was done by Dighem Limited, Suite 7010, 1 First Canadian Place, Toronto, Ontario between May 9th and May 21st, 1981. Base of operations for the survey was at Rancheria, Y.T.

The Midway property straddles the B.C./Yukon border approximately 90 kilometres west of Watson Lake, Y.T. at latitude 60<sup>0</sup>00'N and longitude 130<sup>0</sup>10'W (NTS 105B and NTS 1040).

The property consists of 240 claims in the Watson Lake Mining District, Y.T. and 39 claims and one fractional claim in the Liard Mining Division, British Columbia. A summary of the claim status is shown below.

OWNER: AMAX of Canada Limited

Access to the property is gained via a four-wheel drive road which departs from the Alaska Highway at milepost 701.6. The road extends approximately 13 kilometres south of the B.C./Yukon border to about the midpoint of the west side of the property. From there, a bulldozer track continues south to the south end of the claim group.

The property is underlain by Mississippian argillites, sandstones and coarse clastics of the Lower Sylvester Formation, which lie stratigraphically between McDame Formation carbonates and Upper Sylvester Formation volcanic rocks. Siliceous, pyritic and baritic exhalites, thought to be distal equivalents to Pb-Zn-Ag-Ba mineralization occur within the argillite. A stratiform sphalerite-galena-pyrite showing has been identified on the Bull 3 claim (B.C.).

The Lower Sylvester Formation rocks strike northwest and occupy the central part of a broad northwesterly trending syncline. Stratigraphy dips at 10 to 30<sup>o</sup> northeast and southwest toward the center of the structure. Numerous high angle faults cut stratigraphy, with vertical displacements of up to several hundred metres. A detailed account of property geology appears in a separate 1981 property geological and geochemical assessment report.

The objectives of the electromagnetic/magnetic survey were to; 1) investigate for the presence of massive sulphides, 2) identify and trace the favourable shale horizons and, 3) map regional geology and structure in a general way to assist in orienting more detailed surface evaluation work.

The property is under option to AMAX of Canada from Regional Resources Ltd. Work on the property was managed by Cordilleran Engineering on Regional Resource Ltd's behalf with assistance given by AMAX personnel.

#### EQUIPMENT AND PROCEDURE

The survey was carried out with the Dighem II electromagnetic system. The Dighem system consists of two pairs of transmitter/receiver coils oriented in coaxial (standard) and coplanar (whale tail) configurations operating at approximately 900 hertz. The coils are mounted in a ten metre long bird towed approximately 30 metres below a heli-The helicopter used for the survey was an Aerospatiale copter. Lama registration number C-GDEM. Ancilliary equipment consisted of a Sonotek PMH-5010 magnetometer with its sensor approximately 15 metres below the helicopter, a Sperry radio altimeter, Geocam sequence camera, Barringer 8-channel hot-pen analog recorder, and a Sonotek SDS 1200 digital data acquisition system with a Digi-Data D1130 9-track 800-bpi magnetic tape The analog equipment recorded four channels of EM recorder. data, two ambient EM noise channels (for the coaxial and coplanar receivers), and one channel each of magnetics and radio altitude. The digital equipment recorded the EM data with a sensitivity of 0.20 ppm/bit and the magnetic field to one gamma/bit.

Line spacing for the survey was 300 metres flown at an average bird height of 38 metres at an average airspeed of 103 kilometres per hour. Navigation was achieved visually using a 1:20,000 scale airphoto mosaic.

#### DATA PROCESSING

The data recorded by the survey was subjected to several computer processing steps to improve recognition of bedrock anomalies.

The processing steps include digital band pass filtering of the magnetic data and calculation of electromagnetic difference channels to subdue the effects of conductive overburden. The outputs of the coaxial coils are used to calculate the conductance and depth to the cause of each anomaly using two models, a vertical thin sheet and a horizontal thin sheet and the apparent resistivity and depth to a conductive earth.

The outputs of the coplanar coils are used to calculate the apparent resistivity of the ground in a continuous manner. The model used is a 'pseudo half-space' that is, a conductive half-space overlain by a resistive layer. The details of this and the other processing steps and the significance of the various calculated parameters are discussed in Appendix A.

Recorded data and calculated parameters are plotted in stacked profiles adjusted for variations in speed of the helicopter, at a scale compatible with the airphoto mosaic compilation map.

The computer generated profiles, rather than the original analog records, are used in the evaluation and interpretation of the results in this report.

#### PRESENTATION OF RESULTS

The results of the survey, electromagnetics, resistivity, magnetics and enhanced (filtered) magnetics, are presented in plan superimposed on a 1:15,000 scale airphoto mosaic. For convenience in handling the map is divided into three sheets.

Anomalies are located on the electromagnetic by various symbols which depict the quality and additional essential characteristics. The symbols are labelled with an alphabetic indentifier and conductance and depth for the vertical thin sheet model. Amplitude of each anomaly, conductance and estimated depth for the vertical thin sheet models and apparent resistivity and estimated depth for the conductive earth model are listed in Appendix B. Details of the grading and labelling system used by Dighem are described in Appendix C.

The magnetic and enhanced magnetic data are presented in contoured form using 25 and 100 gamma intervals respectively. The larger contour interval for the enhanced magnetics results from a 20 lines amplification imparted to the data by the filter operator (see discussion of magnetics in Appendix C).

The resistivity results are contoured at logarithmic intervals of 1, 1.3, 1.7, 2.3, 3.1, 4.2, 5.6, 7.5, 10.0 etc to accommodate the large resistivity range. The data are cut-off at one ohm-m and 1,000 ohm-m, the low and high sensitivity limits of the system. Numerical labels on the contours 'point' in the direction of increasing resistivity.

#### RESULTS

An abundance of anomalies were detected by the survey. Line to line correlation of the anomalies to show strike length and direction of the conductors was hampered by the variable character and numbers of the anomalies and the lack of guidance provided by the bland magnetic activity in the area. The trends of the conductors shown on the electromagnetic map were largely determined by use of the resistivity contour patterns. Most of the conductors are long, wide and gently dipping and a majority of them are located at some depth below the surface. There is no evidence that conductive overburden contributes to the electromagnetic response of the area.

There is minimal magnetic activity in the area and only a few anomalies have direct magnetic correlation.

Resistivities range from one ohm-m to 1,000 ohm-m. Most of the area is moderately to highly conductive, resistive areas greater than 1,000 ohm-m are restricted to the east and west edges of the area and occasional small closures elsewhere.

In selecting anomalies for ground follow-up an EM conductor and a coincident resistivity low were considered favourable criteria. A resistivity low alone was not considered a worthwhile target because it could be caused by high background EM response lacking a discrete peak. An example of this type of response occurs at the west end of line 32 on sheet two. Short strike length was also considered a favourable criterion.

Anomalies judged as worthwhile targets are listed below.

<u>Anomaly 43E</u> - A wide conductor which correlates with an interesting 50 gamma magnetic anomaly. The conductor extends to 44E and 42B but magnetic correlation degrades to flanking.

- <u>Anomaly 45B-46A</u> A wide conductor associated with a discrete two line magnetic closure. The resistivity map suggests that the conductor extends south through anomaly 41B.
- <u>Anomaly 46E-48E</u> A wide variable conductor on a steep magnetic gradient. The anomaly probably extends to 44C where it correlates with a distinctive magnetic anomaly.
- <u>Anomaly 54C-56D</u> A good conductor which correlates with an intense resistivity low. Several conductors immediately to the east have similar characteristics.
- Anomaly 54H-56H A conductor situated on the east edge of a resistivity low. The asymmetry of the resistivity low suggests a westward dipping feature.
- Other Anomalies Anomalies 44U, 57Q, 61X, 65N and others associated with resistivity lows immediately east of the 1,000 ohm-m resistivity contour.

#### Sheet 2

<u>Anomaly 1400G-157</u> - A short good conductor which correlates with a 10 gamma magnetic anomaly not displayed by the magnetic contour map because of the coarse contour interval used.

- <u>Anomaly 251</u> A highly resolved EM response on the edge of a large resistivity low. Anomaly 3000D has similar characteristics.
- <u>Anomaly 18F</u> A broad but strong conductor with essentially no out-of-phase response. The anomaly is part of a long conductor which extends for several kilometres to Anomaly 2C on the west side of the area.
- <u>Anomaly 12A-14A</u> Modest anomalies which reflect a 'compact' conductor on a well defined resistivity low.
- Other Anomalies Other anomalies which reflect discrete conductors are 23A-25C, 28F-29C and 32D-34D.

#### Sheet 3

- <u>Anomaly 21I-25E</u> An isolated conductor with a distinct resistivity low with a westerly dip.
- Anomaly 35J-35K A pair of single weak anomalies which have generated a small resistivity low.
- Anomaly 28A-29B, C Modest anomalies associated with a small magnetic closure. The anomalies reflect a wide source.

#### DISCUSSION OF RESULTS

The variations in the resistivity reflect the variable carbon content in the sedimentary lithologies. The zones of lowest resistivity (say less than 10 ohm-m), in general, correlate with the known graphitic shales which host the barite and exhalite horizons and the known massive sulphide horizon. The low resistivity zones are concentrated along the west and east sides of the area, in particular at the southwest end of the area where a broad resistivity low suggests the favourable shale horizon is several hundred metres thick.

The zones of high resistivity (greater than 1,000 ohm-m) at the margins of the area reflect carbonate rocks. Isolated closures elsewhere in the area reflect either faulted blocks of carbonates or in some cases volcanic rocks, the youngest member of the Sylvester Group. In many cases, especially at the margins of the area, the juxtaposition of high and low resistivity serves to identify the location of faults.

Most of the electromagnetic anomalies reflect long, wide (or multiple) conductors characteristic of conductive lithologies. None of the anomalies detected by the survey can be readily attributed to a massive sulphide conductor. The combination of conductors and resistivity lows outline the most graphitic shale units and therefore may assist in focussing ground examination.

The bland magnetic response of the area is consistent with the low magnetic susceptibility of sedimentary rocks. Several small magnetic closures, emphasized by the enhanced magnetics, associated with the conductive trends along the east side of the area are unique because of the general absence of magnetic activity elsewhere on the property. If these anomalies are caused by pyrrhotite, they may indirectly indicate the presence of more desirable sulphide minerals, although the known mineralization is devoid of magnetic minerals.

## APPENDIX A

## THE FLIGHT RECORD AND PATH RECOVERY

## <u>APPENDIX</u> A

## THE FLIGHT RECORD AND PATH RECOVERY

Both analog and digital flight records are produced. The analog profiles are recorded on green chart paper in the aircraft during the survey. The digital profiles are generated later by computer and plotted on grey chart paper at a scale usually identical to the geophysical maps. The digital profiles, which may be displayed, are as follows:

( Number	Channel 7 Labe	1 Parameter	Scale units/mm	<u>Noise</u>
20 21 22 23 24 25 26 27 28 29 33 34 35 36 37 40 41 45	MAG ALT CXI CXQ CPI CPQ VLFT VLFQ CXS CPS DIFI DIFQ REC1 REC2 SIGT RES2 DP RES2	<pre>magnetometer bird height coaxial coil-pair inphase coaxial coil-pair guadrature coplanar coil-pair guadrature vLF-EM total field VLF-EM vertical guadrature ambient noise monitor (coaxial coil) ambient noise monitor (coplanar coil) difference function inphase difference function guadrature first anomaly recognition function second anomaly recognition function conductance log resistivity at main frequency apparent depth at main frequency log resistivity at secondary frequency</pre>	10 gamma 10 feet 1 ppm 1 ppm 1 ppm 1 ppm 1 \$ 1 \$ 1 ppm 1 mho .03 decade 3 m	2 garma 5 feet 1-2 ppm 1-2 ppm 1-2 ppm 1-2 ppm 1-2 % 1-2 % 1 ppm 1-2 ppm 1-2 ppm 1-2 ppm 1-2 ppm 1-2 ppm

Note: Channels 42 to 44 are experimental.

The log resistivity scale of 0.03 decade/mm means that the resistivity changes by an order of magnitude in 33 mm. The resistivities at 0, 33, 67 and 100 mm up from the bottom of the chart are respectively 1, 10, 100 and 1000 ohm-m.

The fiducial marks on the flight records represent points on the ground which were recognized by the aircraft navigator. Continuous photographic coverage allowed accurate photo-path recovery locations for the fiducials, which were then plotted on the geophysical maps to provide the track of the aircraft.

The fiducial locations on both the flight records and flight path maps were examined by a computer for unusual helicopter speed changes. Such changes may denote an error in flight path recovery. The resulting flight path locations therefore reflect a more stringent checking than is provided by standard flight path recovery techniques.

The following brief description of DIGHEM<sup>II</sup> illustrates the information content of the various profiles\*.

**(ii)** 

<sup>\*</sup>For a detailed description, see D.C. Fraser, Geophysics, v.44, p.1367-1394.

#### Single-frequency surveying

The DIGHEM<sup>II</sup> system has two transmitter coils which are mounted at right angles to each other. Both coils transmit at approximately the same frequency. (This frequency is given in the Introduction.) Thus, the system provides two completely independent surveys at one pass. In addition, the digital flight chart profiles (generated by computer) include an inphase channel and a quadrature channel which essentially are free of the response of conductive overburden. Also, the EM channels may indicate whether the conductor is thin (e.g., less than 3 m), or has a substantial width (e.g., greater than 10 m). Further, the EM channels include channels of resistivity, apparent depth and conductance. A minimum of 11 EM channels are provided. The DIGHEM<sup>II</sup> system therefore gives information in one pass which cannot be obtained by any other airborne or ground EM technique.

Figure Al shows a DIGHEM<sup>II</sup> flight profile over the massive pyrrhotite ore body in Montcalm Township, Ontario. It will serve to identify the majority of the available channels.

Fig. Al. Flight over Montcalm deposit, with line parallel to strike

.

The two upper channels (numbered 20 and 21) are respectively the magnetics and the radio altitude. Channels 22 and 23 are respectively the inphase and quadrature of the coaxial coil-pair, which is termed the <u>standard</u> coil-pair. This coil-pair is equivalent to the standard coil-pair of all inphase-quadrature airborne EM systems. Channels 24 and 25 are the inphase and quadrature of the additional coplanar coil-pair which is termed the whaletail coil-pair.

Channels 31 and 32 are inphase and quadrature sum functions of the standard and whaletail channels; they provide a condensed view of the four basic channels 22 to 25. The sum channels normally are not plotted.

Channels 33 and 34 are inphase and quadrature difference functions of the standard and whaletail channels. The difference channels are almost free from the response of conductive overburden. Channel 37 is the conductance. The conductance channel essentially is an automatic anomaly picker calibrated in conductance units of mhos; it is triggered by the anomaly recognition functions shown as channels 35 and 36. Channel 40 is the resistivity, which is derived from the whaletail channels 24 and 25. The resistivity channel 40 yields data which can be contoured, and so the DIGHEM<sup>II</sup> system yields a resistivity contour map in addition to an electromagnetic map, a magnetic contour map, and an enhanced magnetic contour map. The enhanced magnetic contour map is similar to the filtered magnetic map discussed by Fraser.\*

Figure A2 presents the DIGHEM<sup>II</sup> results for a line flown perpendicularly to the Montcalm ore body. Channel 20 shows the 175 gamma magnetic anomaly caused by the massive pyrrhotite deposit. For the EM channels, the following points are of interest:

 On channels 22-25 and 31-34, the ore body essentially yields only an inphase response. The quadrature response is almost completely caused by conductive overburden (which also gives a small inphase response). The hachures show the EM response from the overburden. The overburden response vanishes on the

\*Cdn. Inst. Mng., Bull., April 1974.

Fig. A2. Flight over Montcalm deposit, with line perpendicular to strike.

difference EM channels, as can be seen by comparing the quadrature channels 25 and 34. This is an important point to note because DIGHEM<sup>II</sup> is the only EM system which provides an inphase channel and a quadrature channel which are essentially free of conductive overburden response.

- 2. The whaletail anomaly of channel 24 has a single peak. This shows that the conductor has a substantial width. If the width had been under 3 m, the conductor would have produced a weak m-shaped anomaly on channel 24.
- 3. The ore body yields a resistivity of 5 ohm-m in a background of about 200 ohm-m (cf. channel 40). A dipole-dipole ground resistivity survey with an a-spacing of 50 m showed a similar background, but the ore body gave a low of only 53 ohm-m because of the averaging effect inherent in the ground technique.
- 4. The ore body has a conductance of 330 mhos according to its EM response on this particular flight line. The conductance channel 37 saturates at 100 mhos, and so the deposit is indicated by a 100-mho spike.

(viii)

Figure Al illustrates the DIGHEM<sup>II</sup> results for a line flown subparallel to the ore body. The ore body anomaly is small on the standard coil-pair (channel 22) but shows up strongly on the whaletail coil-pair (channel 24).

#### Dual-frequency surveying

For surveys flown primarily for resistivity mapping, as opposed to EM surveying, the two transmitter coils may be energized at two well-separated frequencies (e.g., 900 and 3600 Hz). Apparent resistivity and apparent depth maps can be made independently for each frequency. The interpretation procedure involves comparing the apparent resistivities and apparent depths at the two frequencies.

The use of two different coil-pair orientations (i.e., standard and whaletail) for dual-frequency resistivity mapping is an unorthodox procedure. However, as long as the current flow patterns are primarily horizontal, the different coil orientations do not influence the results, according to superposed dipole theory. Wire fences and other cultural features will produce local deviations,

because they usually respond preferentially to one or the other of the coil-pairs.

The difference channels 33 and 34 are not produced because the divergent frequencies of the two coil-pairs renders them meaningless. In addition, channels 35 to 37 also are not produced.

APPENDIX C

ELECTROMAGNETICS AND MAGNETICS

r

#### ELECTROMAGNETICS

DIGHEM electromagnetic responses fall into two general classes, discrete and broad. The discrete class consists of sharp, well defined anomalies from discrete conductors such as sulfide lenses and steeply dipping sheets of graphite and sulfides. The broad class consists of wide anomalies from conductors having a large horizontal surface such as flatly dipping graphite or sulfide sheets, saline water-saturated sedimentary formations, conductive overburden and rock, and geothermal zones. A vertical conductive slab with a width of 100 m would straddle these two classes.

The vertical sheet (half plane) is the most common model used for the analysis of discrete conductors. All anomalies plotted on the electromagnetic map are interpreted according to this model. The following section entitled <u>Discrete conductor analysis</u> describes this model in detail, including the effect of using it on anomalies caused by broad conductors such as conductive overburden.

The conductive earth (half space) model is suitable for broad conductors. Resistivity contour maps result from the use of this model. A later section entitled <u>Resistivity</u> <u>mapping</u> describes the method further, including the effect of using it on anomalies caused by discrete conductors such as sulfide bodies.

#### Discrete conductor analysis

The EM anomalies appearing on the electromagnetic map are interpreted by computer to give the conductance (i.e., conductivity-thickness product) in mhos of a vertical sheet model. DIGHEM anomalies are divided into six grades of conductance, as shown in Table I. The conductance in mhos is the reciprocal of resistance in ohms.

Anomaly Grade	Mho Range
6	greater than 99
5	50 — 99
4	20 - 49
3	10 - 19
2	5 - 9
1 '	less than 5

The mho value is a geological parameter because it is a characteristic of the conductor alone; it generally is independent of frequency, and of flying height or depth of burial apart from the averaging over a greater portion of the conductor as height increases.<sup>1</sup> Small anomalies from deeply buried strong conductors are not confused with small anomalies from shallow weak conductors because the former will have larger mho values.

Conductive overburden generally produces broad EM responses which are not plotted on the EM maps. However, patchy conductive overburden in otherwise resistive areas can yield discrete-like anomalies with a conductance grade (cf. Table I) of 1, or even of 2 for conducting clays which have resistivities as low as 50 ohm-m. In areas where ground resistivities can be as low as 1 ohm-m, anomalies caused by weathering variations and similar causes can have conductance grades as high as 4. The anomaly shapes from the multiple coils often allow such surface conductors to be recognized, and these are indicated by the letter S on the map. The remaining anomalies in such areas could be

This statement is an approximation. DIGHEM, with its short coil separation, tends to yield larger and more accurate mho values than airborne systems having a larger coil separation. bedrock conductors. The higher grades indicate increasingly higher conductances. Examples: DIGHEM's New Insco copper discovery (Noranda, Quebec, Canada) yielded a grade 4 anomaly, as did the neighbouring copper-zinc Magusi River ore body; Mattabi (copper-zinc, Sturgeon Lake, Ontario, Canada) and Whistle (nickel, Sudbury, Ontario, Canada) gave grade 5; and DIGHEM's Montcalm nickel-copper discovery (Timmins, Ontario, Canada) yielded a grade 6 anomaly. Graphite and sulfides can span all grades but, in any particular survey area, field work may show that the different grades indicate different types of conductors.

Strong conductors (i.e., grades 5 and 6) are characteristic of massive sulfides or graphite. Moderate conductors (grades 3 and 4) typically reflect sulfides of a less massive character or graphite, while weak bedrock conductors (grades 1 and 2) can signify poorly connected graphite or heavily disseminated sulfides. Grade 1 conductors may not respond to ground EM equipment using frequencies less than 2000 Hz.

The presence of sphalerite or gangue can result in ore deposits having weak to moderate conductances. As an example, the three million ton lead-zinc deposit of Restigouche Mining Corporation near Bathurst, New Brunswick, Canada, yielded a well defined grade 1 conductor. The 10 percent by volume of sphalerite occurs as a coating around the fine grained massive pyrite, thereby inhibiting electrical conduction.

Faults, fractures and shear zones may produce anomalies which typically have low conductances (e.g., grade 1 and 2). Conductive rock formations can yield anomalies of any conductance grade. The conductive materials in such rock formations can be salt water, weathered products such as clays, original depositional clays, and carbonaceous material.

On the electromagnetic map, the actual mho value and a letter are plotted beside the EM grade symbol. The letter is the anomaly identifier. The horizontal rows of dots, beside each anomaly symbol, indicate the anomaly amplitude on the flight record. The vertical column of dots gives the estimated depth. In areas where anomalies are crowded, the identifiers, dots and mho values may be obliterated. The EM grade symbols, however, will always be discernible, and the obliterated information can be obtained from the anomaly listing appended to this report. The purpose of indicating the anomaly amplitude by dots is to provide an estimate of the reliability of the conductance calculation. Thus, a conductance value obtained from a large ppm anomaly (3 or 4 dots) will be accurate whereas one obtained from a small ppm anomaly (no dots) could be inaccurate. The absence of amplitude dots indicates that the anomaly from the coaxial coil-pair is 5 ppm or less on both the inphase and quadrature channels. Such small anomalies could reflect a weak conductor at the surface or a stronger conductor at depth. The mho value and depth estimate will illustrate which of these possibilities fits the recorded data best.

Flight line deviations occasionally yield cases where two anomalies, having similar mho values but dramatically different depth estimates, occur close together on the same conductor. Such examples illustrate the reliability of the conductance measurement while showing that the depth estimate can be unreliable. There are a number of factors which can produce an error in the depth estimate, including the averaging of topographic variations by the altimeter, overlying conductive overburden, and the location and attitude of the conductor relative to the flight line. Conductor location and attitude can provide an erroneous depth estimate because the stronger part of the conductor may be deeper or to one side of the flight line, or because it has a shallow dip. A heavy tree cover can also produce errors in depth estimates. This is because the depth estimate is computed as the distance of bird from conductor, minus the altimeter reading. The altimeter can lock on the top of a dense forest canopy. This situation yields an erroneously large depth estimate but does not affect the conductance estimate.

Dip symbols are used to indicate the direction of dip of conductors. These symbols are used only when the anomaly shapes are unambiguous, which usually requires a fairly resistive environment.

A further interpretation is presented on the EM map by means of the line-to-line correlation of anomalies, which is based on a comparison of anomaly shapes on adjacent lines. This provides conductor axes which may define the geological structure over portions of the survey area. The absence of conductor axes in an area implies that anomalies could not be correlated from line to line with reasonable confidence.

DIGHEM electromagnetic maps are designed to provide a correct impression of conductor quality by means of the conductance grade symbols. The symbols can stand alone with geology when planning a follow-up program. The actual mho values are plotted for those who wish quantitative data. The anomaly ppm and depth are indicated by inconspicuous dots which should not distract from the conductor patterns, while being helpful to those who wish this information. The map provides an interpretation of conductors in terms of length, strike direction, conductance, depth, thickness (see below), and dip. The accuracy is comparable to an interpretation from a ground EM survey having the same line spacing.

An EM anomaly list attached to each survey report provides a tabulation of anomalies in ppm, and in mhos and estimated depth for the vertical sheet model. The EM anomaly list also shows the conductance in mhos and the depth for a thin horizontal sheet (whole plane) model, but only the vertical sheet parameters appear on the EM map. The horizontal sheet model is suitable for a flatly dipping thin bedrock conductor such as a sulfide sheet having a thickness less than 15 m. The list also shows the resistivity and depth for a conductive earth (half space) model, which is suitable for thicker slabs such as thick conductive overburden. In the EM anomaly list, a depth value of zero for the conductive earth model, in an area of thick cover, warns that the anomaly may be caused by conductive overburden.

Since discrete bodies normally are the targets of EM surveys, local base (or zero) levels are used to compute local anomaly amplitudes. This contrasts with the use of true zero levels which are used to compute true EM amplitudes. Local anomaly amplitudes are shown in the EM anomaly list and these are used to compute the vertical sheet parameters of conductance and depth. Not shown in the EM anomaly list are the true amplitudes which are used to compute the horizontal sheet and conductive earth parameters.

#### X-type electromagnetic responses

DIGHEM<sup>II</sup> maps contain x-type EM responses in addition to EM anomalies. An x-type response is below the noise threshold of 2 ppm, and reflects one of the following: a weak conductor near the surface, a strong conductor at depth (e.g., 100 to 120 m below surface) or to one side of a flight line, or aerodynamic noise. Those responses that have the appearance of valid bedrock anomalies on the flight profiles are mentioned in the report. The others should not be followed up unless their locations are of considerable geological interest.

### The thickness parameter

DIGHEM<sup>II</sup> can provide an indication of the thickness of a steeply dipping conductor. The ratio of the anomaly amplitude of channel 24/channel 22 generally increases as the apparent thickness increases, i.e., the thickness in the horizontal plane. This thickness is equal to the conductor width if the conductor dips at 90 degrees and strikes at right angles to the flight line. This report refers to a conductor as thin when the thickness is likely to be less than 3m, and thick when in excess of 10 m. In base metal exploration applications, thick conductors can be high priority targets because most massive sulfide orc bodies are thick, whereas non-economic bedrock conductors are usually thin. An estimate of thickness cannot be obtained when the strike of the conductor is subparallel to the flight line, when the conductor has a shallow dip, when the anomaly amplitudes are small, or when the resistivity of the environment is below 100 ohm-m.

#### Resistivity mapping

Areas of widespread conductivity are commonly encountered during surveys. In such areas, anomalies can be generated by decreases of only 5 m in survey altitude as well as by increases in conductivity. The typical flight record in conductive areas is characterized by inphase and quadrature channels which are continuously active; local peaks reflect either increases in conductivity of the earth or decreases in survey altitude. For such conductive areas, apparent resistivity profiles and contour maps are necessary for the interpretation of the airborne data. The advantage of the resistivity parameter is that anomalies caused by altitude changes are virtually eliminated, so the resistivity data reflect only those anomalies caused by conductivity changes. This helps the interpreter to differentiate between conductive trends in the bedrock and those patterns typical of conductive overburden. Discrete conductors will generally appear as narrow lows on the contour map and broad conductors will appear as wide lows.

Channel 40 (see Appendix) and the resistivity contour map present the apparent resistivity using the so-called pseudo-layer (or buried) half space model defined in Fraser (1978)<sup>2</sup>. This model consists of a resistive layer overlying a conductive half space. Channel 41 gives the apparent depth below surface of the conductive material.

<sup>&</sup>lt;sup>2</sup>Resistivity mapping with an airborne multicoil electromagnetic system: Geophysics, v 43, p. 144-172.

The apparent depth therefore is simply the apparent thickness of the overlying resistive layer. The apparent depth (or thickness) parameter will be positive when the upper layer is more resistive than the underlying material, in which case the apparent depth may be quite close to the true depth.

The apparent depth will be negative when the upper layer is more conductive than the underlying material, and will be zero when a homogeneous half space exists. The apparent depth parameter must be interpreted cautiously because it will contain any errors which may exist in the measured altitude of the EM bird (e.g., as caused by a dense tree cover). The inputs to the resistivity algorithm are the inphase and quadrature components of the coplanar coilpair. The outputs are the apparent resistivity of the conductive half space (the source) and the sensor-source distance. The flying height is not an input variable, and the output resistivity and sensor-source distance are independent of the flying height. The apparent depth, discussed above, is simply the sensor-source distance minus the measured altitude or flying height. Consequently, errors in the measured altitude will affect the apparent depth parameter but not the apparent resistivity parameter.

The apparent depth parameter is a useful indicator of simple layering in areas lacking a heavy tree cover. The DIGHEM<sup>II</sup> system has been flown for the purpose of permafrost mapping, where positive apparent depths were used as a measure of permafrost thickness. However, little quantitative use has been made of negative apparent depths because the absolute value of the negative depth is not a measure of the thickness of the conductive upper layer and, therefore, is not meaningful physically. Qualitatively, a negative apparent depth estimate usually shows that the EM anomaly is caused by conductive overburden. Consequently, the apparent depth channel 41 can be of significant help in distinguishing between overburden and bedrock conductors.

## Interpretation in conductive environments

Environments having background resistivities below 30 ohm-m cause all airborne EM systems to yield very large responses from the conductive ground. This usually prohibits the recognition of bedrock conductors. The processing of DIGHEM<sup>II</sup> data, however, produces four channels which contribute significantly to the recognition of bedrock conductors. These are the inphase and quadrature difference channels (number 33 and 34), and the resistivity and depth channels (40 and 41). The EM difference channels

eliminate up to 99% of the response of conductive ground, leaving responses from bedrock conductors, cultural features (e.g., telephone lines, fences, etc.) and edge effects. An edge effect arises when the conductivity of the ground suddenly changes, and this is a source of geologic noise. While edge effects yield anomalies on the EM difference channels, they do not produce resistivity anomalies. Consequently, the resistivity channel aids in eliminating anomalies due to edge effects. On the other hand, resistivity anomalies will coincide with the most highly conductive sections of conductive ground, and this is another source of geologic noise. The recognition of a bedrock conductor in a highly conductive environment therefore is based on the anomalous responses of the two difference channels (33 and 34) and the resistivity channel (40). The most favourable situation is where anomalies coincide on all three channels.

Channel 41, which is the apparent depth to the conductive material, also helps determine whether a conductive response arises from surficial material or from a conductive zone in the bedrock. When this channel rides above the zero level on the grey profile paper (i.e., it is negative), it implies that the EM and resistivity profiles are responding primarily to a conductive upper layer, i.e., conductive overburden. If channel 41 is below the zero level, it indicates that a resistive upper layer exists, and this usually implies the existence of a bedrock conductor.

Channels 35 and 36 are the anomaly recognition functions. They are used to trigger the conductance channel 37 which identifies discrete conductors. In highly conducting environments, channel 36 may not be generated because it is subject to some corruption by highly conductive earth signals. Some of the automatically selected anomalies (channel 37) are discarded by the human interpreter. The automatic selection algorithm is intentionally oversensitive to assure that no meaningful responses are missed. The interpreter then classifies the anomalies according to their source and eliminates those that are not substantiated by the data, such as those rising from geologic or aerodynamic noise.

The resistivity map often yields more useful information on conductivity distributions than the EM map. In comparing the EM and resistivity maps, keep in mind the following:

(a) The resistivity map portrays the absolute value of the earth's resistivity. (b) The EM map portrays anomalies in the earth's resistivity. An anomaly by definition is a change from the norm and so the EM map displays anomalies, (i) over narrow, conductive bodies and (ii) over the boundary zone between two wide formations of differing conductivity.

The resistivity map might be likened to a total field map and the EM map to a horizontal gradient in the direction of flight<sup>3</sup>. Because gradient maps are usually more sensitive than total field maps, the EM map therefore is to be preferred in resistive areas. However, in conductive areas, the absolute character of the resistivity map usually causes it to be more useful than the EM map.

#### Reduction of geologic noise

Geologic noise refers to unwanted geophysical responses. For purposes of airborne EM surveying, geologic noise refers to EM responses caused by conductive overburden

<sup>&</sup>lt;sup>3</sup>The gradient analogy is only valid with regard to the identification of anomalous locations. The calculation of conductance is based on EM amplitudes relative to a local base level, rather than to an absolute zero level as for the resistivity calculation.
and magnetic polarization. It was mentioned above that the EM difference channels (i.e., channel 33 for inphase and 34 for quadrature) tend to eliminate the response of conductive overburden. This marked a unique development in airborne EM technology, as DIGHEM<sup>II</sup> is the only EM system which yields channels having an exceptionally high degree of immunity to conductive overburden.

Magnetite produces a form of geological noise on the inphase channels of all EM systems. Rocks containing less than 1% magnetite can yield negative inphase anomalies caused by magnetic polarization. When magnetite is widely distributed throughout a survey area, the inphase EM channels may continuously rise and fall reflecting variations in the magnetite percentage, flying height, and overburden thickness. This can lead to difficulties in recognizing deeply buried bedrock conductors, particularly if conductive overburden also exists. However, the response of broadly distributed magnetite generally vanishes on the inphase difference channel 33. This feature can be a significant aid in the recognition of conductors which occur in rocks containing accessory magnetite.

### MAGNETICS

The existence of a magnetic correlation with an EM anomaly is indicated directly on the EM map. An EM anomaly with magnetic correlation has a greater likelihood of being produced by sulfides than one that is non-magnetic. However, sulfide ore bodies may be non-magnetic (e.g., the Kidd Creek deposit near Timmins, Ontario, Canada) as well as magnetic (e.g., the Mattabi deposit near Sturgeon Lake, Ontario).

The magnetometer data are digitally recorded in the aircraft to an accuracy of one gamma. The digital tape is processed by computer to yield a standard total field magnetic map which is usually contoured at 25 gamma intervals. The magnetic data also are treated mathematically to enhance the magnetic response of the near-surface geology, and an enhanced magnetic map is produced with a 100 gamma contour interval. The response of the enhancement operator in the frequency domain is shown in Figure 2. The 100 gamma contour interval is equivalent to a 5 gamma interval for the passband components of the airborne data. This is because these components are amplified 20 times by the operator of Figure 2. AMPLITUDE

CYCLES /-FOOT

Figure 2

Frequency response of magnetic operator

The enhanced map, which bears a resemblance to a downward continuation map, is produced by digital bandpass filtering the total field data. The enhancement is equivalent to continuing the field downward to a level (above the source) which is 1/20th of the actual sensor-source distance.

Because the enhanced magnetic map bears a resemblance to a ground magnetic map, it simplifies the recognition of trends in the rock strata and the interpretation of geological structure. The contour interval of 100 gammas is suitable for defining the near-surface local geology while de-emphasizing deep-seated regional features. APPENDIX D

STATEMENT OF COSTS

## STATEMENT OF COSTS

Midway Property - Geophysical Assessment Report

Work Period: May 9 - May 21, 1981

Airborne Electromagnetic Survey - Dighem Limited, Toronto

Ferry/mobilization	\$10,000.00
Survey 778 km @ 53/km	41,234.00
Total	\$51,234.00

Contractor's invoices and disposition of costs are contained in: 1981 Geological and Geochemical Report on the Midway Property.

# APPENDIX E

# STATEMENT OF QUALIFICATIONS

## STATEMENT OF QUALIFICATIONS

NAME: J. LAURENCE LEBEL

EDUCATION: B.Sc. (1971) Queen's University - Geological Engineering -Geophysics Option

M.Sc (1973) University of Manitoba - Geophysics

#### EXPERIENCE:

- 5/70-9/70 Amax Exploration, Inc. Vancouver, B.C. - conducting and compiling magnetometer surveys
- 5/71-9/71 Amax Exploration, Inc. Toronto, Ont. - conducting and reporting on IP/resistivity surveys

### 5/72-12/72- Gulf Minerals, Toronto, Ont.

- senior geophysical operator
- conducting and reporting on magnetometer electromagnetic and scintillometer surveys
- 3/73-12/73- Scintrex Surveys, Concord, Ont.
  - Junior Geophysicist
  - conducting, supervising of and reporting on airborne magnetometer and electromagnetic surveys, ground electromagnetic and IP/resistivity surveys
- 4/74 - AMAX of Canada Limited Toronto & Vancouver - Staff Geophysicist
