1 INTRODUCTION

This report presents the results of geochemical soil sampling on the Whipsaw claims, located in the Cariboo Mining Division of central B.C. The Whipsaw property consists of eight mineral claims owned by K. Vincent Campbell of Wells, B.C. and staked in 1980.

The geological setting is such that there is a potential for two types of mineral deposits; gold and silver-bearing quartz veins and auriferous pyritic replacement bodies in limestone, as occur at the currently active Mosquito Creek Gold Mine some 2½ km to the southeast along the regional strike. At that mine site the ore-bearing horizon occurs near a particular rock unit contact which passes through the Whipsaw property. A VLF-EM survey performed in 1981 resulted in an interpretation of the location of this geological contact.

The geological soil sampling program of 1981 and 1982 had the objectives of (1) verifying the location of the inferred geological contact, and (2) testing for the presence of geochemical anomalies in soils over the rock unit contact area, the latter being the most favorable for mineralization.

The geochemical soil sampling was done in September 1981 and June 1982. Ten man-days were spent on the collection of 223 samples. One man-day was spent on cutting 3/4 km of trail along the location line. In addition, 4½ km of VLF-EM survey were completed in September, 1981. The geophysical results were included in the 1981 assessment report and the costs of this geophysical work, done after the 1981 anniversary of the recording date, are claimed as part of the current assessment report.

1.1 Location and Access

The Whipsaw claims, Whipsaw 1 to 8 inclusive, are located in National Topographic System map area 93H/4E and are 5 km northwest of the village of Wells, B.C., west of Barkerville (Figure 1), and 80 km east of Quesnel on Highway 26. The claims lie on the north side of Island Mtn., south of the Willow River.

Access to the property is by 4 wheel drive along Hardscrabble Road from Wells (Figure 3) and then by foot across the Willow River and walking about ½ km upslope to the location line.

1.2 Ownership and Claims Status

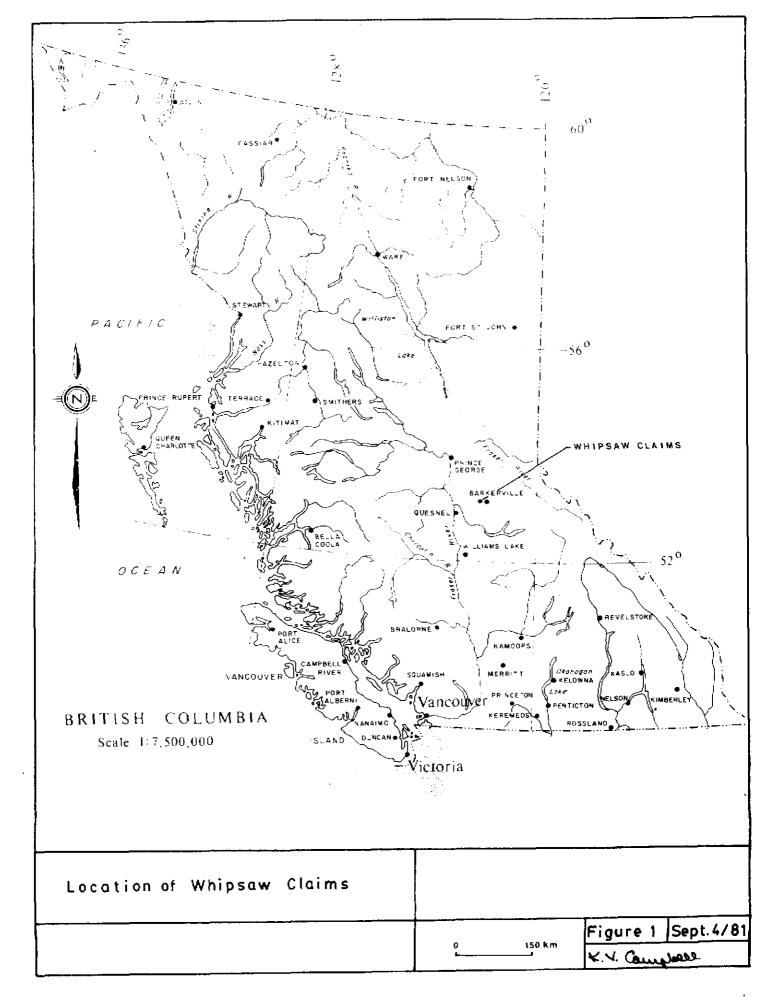

The property consists of eight 2-post mineral claims in the Cariboo Mining Division. Figure 2 is a copy of the mineral titles map M 93H/4E showing the Whipsaw claims. The claim information is as follows.

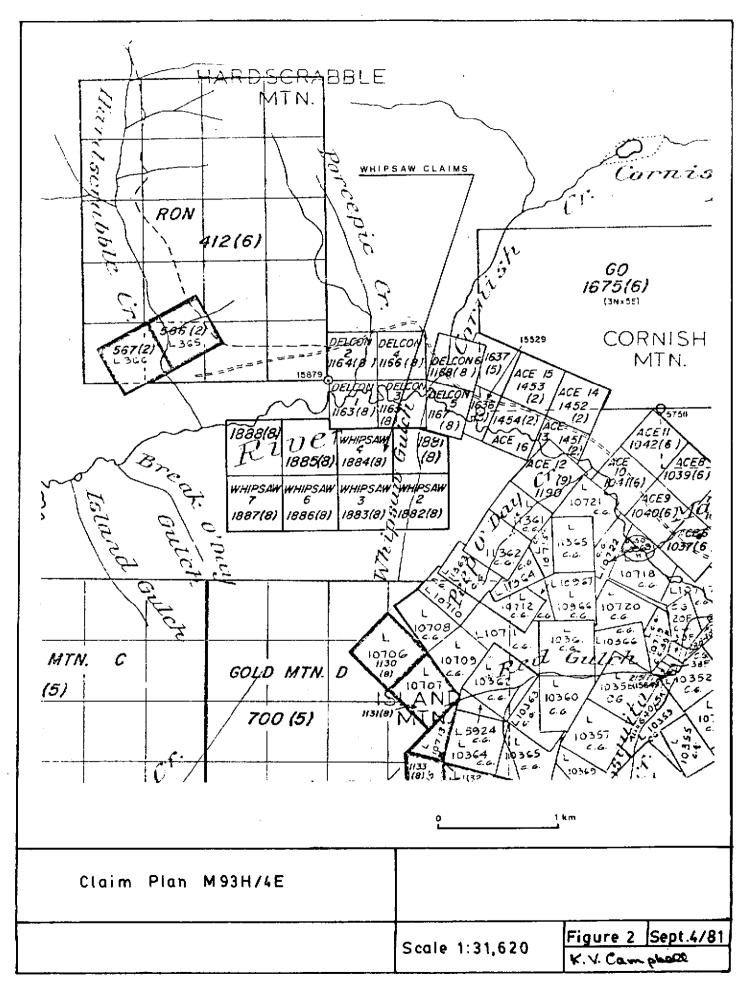

<u>Claim Name</u>	Record No.	Recording Date	Recorded Holder
Whipsaw l	1881	August 25,1982	K.V. Campbell

1.4 History

1.4.1 Regional

The Cariboo area is the oldest mining camp in British Columbia, the first prospectors arriving c.1858. The early miners focused on placer deposits but by the 1880's

gold-quartz veins were being mined. Historical lode gold mines located 3 to 10 km to the southeast of Whipsaw Gulch are the Island Mtn., Cariboo Gold Quartz, Canusa and Williams Creek Gold Mines. Gold was won from both gold-quartz veins and pyritic replacement bodies in limestone. Free goldbearing quartz veins also occur at the Hardscrabble tungsten mine site $\frac{1}{2}$ km to the northwest of Whipsaw Gulch, but these were never mined. The only gold mine producing at the present time in the area is the Mosquito Creek Gold Mine on Mosquito Creek, $2\frac{1}{2}$ km to the southeast of Whipsaw Gulch. All of the foregoing gold mines and the axis of the main placer deposits lie along what is called the Barkerville Gold Belt. The Whipsaw property is at the northwest end of the known extension of this belt.

1.4.2 Property

The Whipsaw claims were staked in mid-August of 1980 because the area straddles the projection of the geology and structure at the Mosquito Creek Gold Mine to the southeast.

No record of earlier mineral claims was found. A hydraulic ditch, now mostly obliterated, crosses the claims in the vicinity of the location line. Presumably it served placer mining activities on Mosquito Creek, c.1930's. This ditch could be upgraded to an access road fairly easily. A cabin site and piles of boulders along the drainageways at the north edge of the claims attest to placer mining there. There are no known mineral showings and few outcrops on the property.

In 1980 and 1981 the streams were prospected, the few outcrops mapped and a VLF-EM survey completed (Campbell and Campbell, 1981). The geophysical findings are summarized in a following section.

2 GEOMORPHOLOGY

2.1 Regional

The property lies within the Quesnel Highland physiographic region. A characteristic of this region are upland areas which are remnants of a highly dissected plateau of moderate relief formed in Tertiary times. The summit of Island Mtn. is one such remnant. Pleistocene ice covered most of the high areas and consequently most summits are rounded. Valley glaciers truncated spurs and deposited materials over much of the area. The valleys that encircle Island Mtn. were accentuated, if not created, by valley glaciers and are floored with glaciofluvial deposits.

2.1 Property

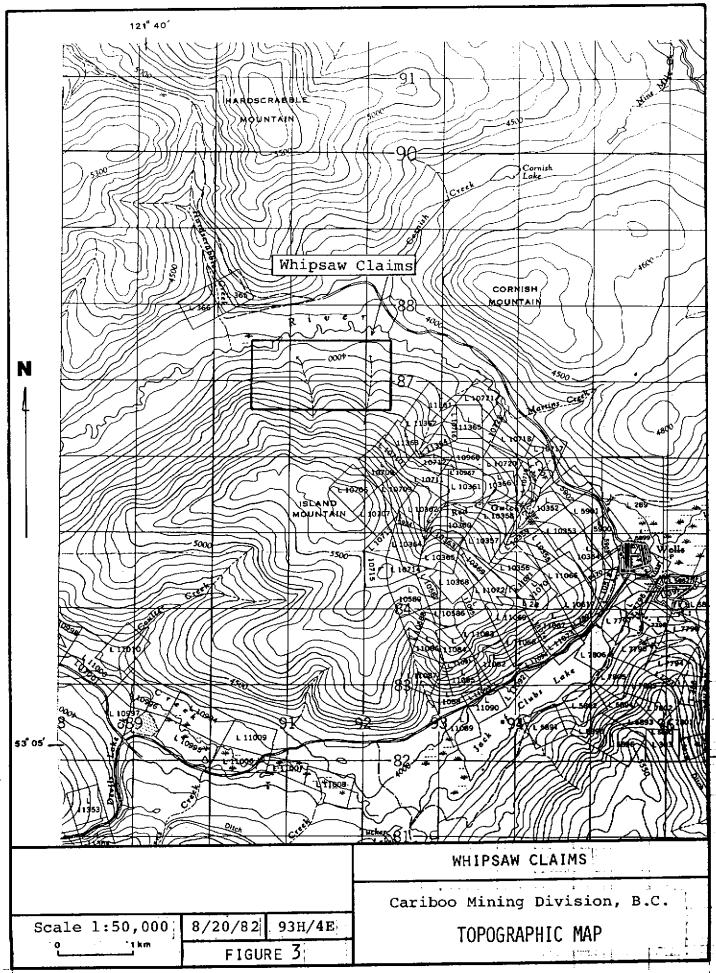

Figure 3 is a topographic map of the claims area. Relief is about 300m (1000 ft). A well developed ridge of lateral moraine lies along the north edge of the claims. On the south side of this ridge is a narrow strip of lacustrine clays and silts with a gently undulating surface. Upslope from this are outwash sand and gravels which extend to the vicinity of the location line. Compacted till and colluvium cover the upper slopes of the claims south of the location line. Coarse angular talus of amphibolite and greenstone occur in the southwest corner of the property.

The claims are thickly timbered with spruce and balsam and there are numerous thickets of willow and alder. Only a few outcrops have been found.

3 GEOLOGY

3.1 Regional

Figure 4 is the most recent interpretation of the regional geology, from Struik, 1981c. Table 1 is the explanation of symbols on this map.

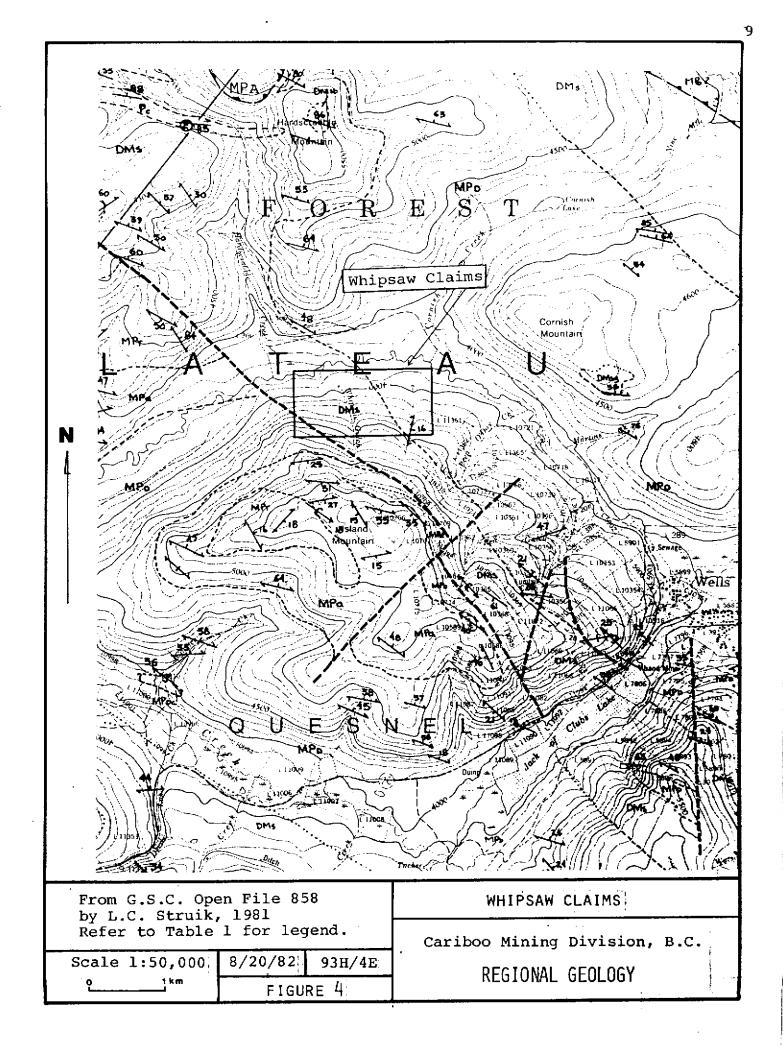

Table 1. Explanation to accompany Figure 4, Regional Geology, by L.C. Struik, 1981(c).

DEVONIAN ? AND MISSISSIPPIAN ?

DMs black siltite and phyllite, gray micaceous quartzite, limestone, minor metatuff ? DMsb graywacke, muddy conglomerate DMsg quartzite clast conglomerate, quartzite

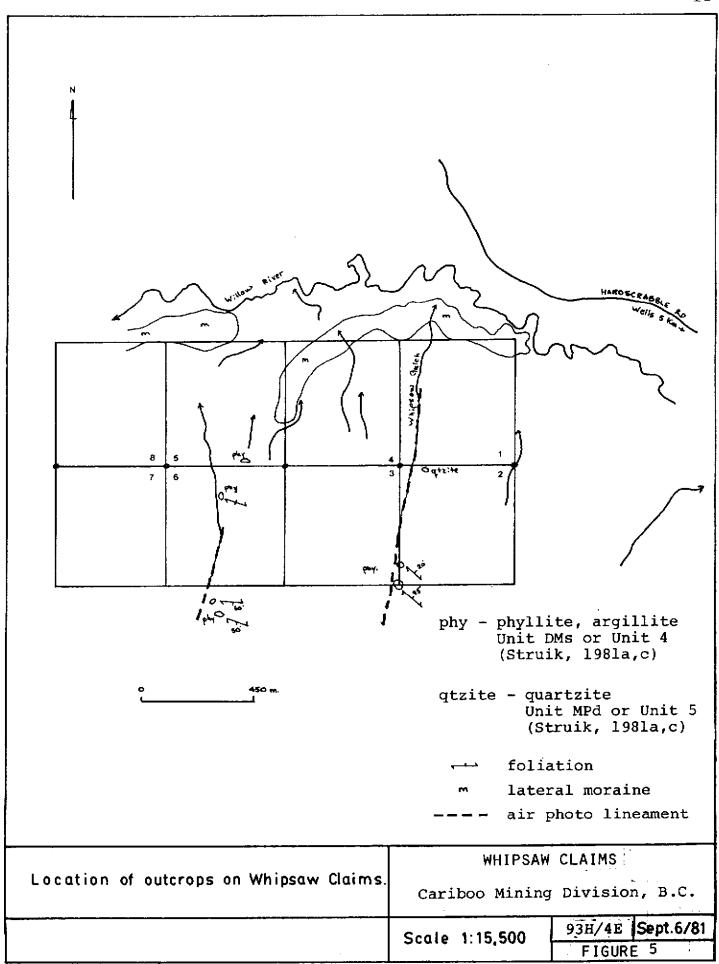

The area lies along the western part of the Omineca Tectonic Belt. Two regional tectonostratigraphic sequences are represented in Figure 4. These are (1) Upper Ordovician to Permian limestone, shale, conglomerate and sandstone represented by units Pc, MPt, MPd, and DMs in Figure 4, and (2) Permian and Pennsylvanian oceanic chert and mafic and ultramafic volcanic and intrusive rocks, unit MPA in Figure 4. The latter sequence, the Antler Formation, has been thrust from the west over the basinal sequence.

Unit DMs, previously referred by Struik (1981a) as Unit 4, is that mapped by Sutherland Brown (1957) as the Midas Formation and known at the Island Mtn. and Mosquito Creek mines as the Rainbow Member. Unit MPd, equivalent to Unit 5 of Struik (1981a), was mapped by Sutherland Brown as the Snowshoe Formation.

In the lower part of unit MPd, above the contact with unit DMs, is a limestone unit known at the gold mines as the Baker Member. More that 95% of the gold production has come from a band less than 1.5 m (5 ft) in width along the contact between the Rainbow and Baker members (Benedict, 1945). The replacement deposits found in this band are pencil-shaped bodies with an average cross-sectional area not much greater than 9 m² (100 ft²). The ore bodies consist almost entirely of fine-grained pyrite with a minor amount of arsenopyrite (Sutherland Brown, 1957).

3.2 Property

Figure 5 shows the location of the few outcrops found on the claims. One broken outcrop of unit MPd, equivalent to Unit 5 of Struik (1981a) occurs near the location line of Whipsaw 1 and 2. The rock is light brownish gray micaceous quartzite with abundant rusty spots, thinly laminated and well foliated. The remainder of the outcrops found are of unit DMs, equivalent to Unit 4 of Struik (1981a) and the Rainbow Member of earlier workers. These rocks are black phyllites and argillites, thinly laminated to thinly bedded, sooty in places and locally very rusty weathering. They dip at moderate to steep angles northeast and southwest. There are at least two cleavages present in addition to the penetrative bedding plane foliation. The rocks have been tightly folded and overturned as well as being extremely The two prominent lineaments are interpreted to be sheared. developed along fractures.

4 GEOPHYSICS

4.1 VLF-EM Survey

The geophysical assessment report of Campbell and Campbell (1981) presented the results of a reconnaissance VLF-EM survey performed in 1981. Figure 6 is a Fraser Filter contour map of the Whipsaw property. The conductor pattern indicates the northwest striking trends of the underlying The region of relatively high conductivity is structure. interpreted to be underlain by black phyllites and argillites The region of relatively low conductivity in of Unit DMs. the northeast part of the claims is thought to be underlain by micaceous guartzites of Unit MPd. This interpretation and the inferred approximate position of the contact between the rock units agrees well with the position of the known outcrops on the claims. The contact location, inferred from the geophysical work, is shown on Figure 8, a compilation and interpretative map.

5 GEOCHEMISTRY

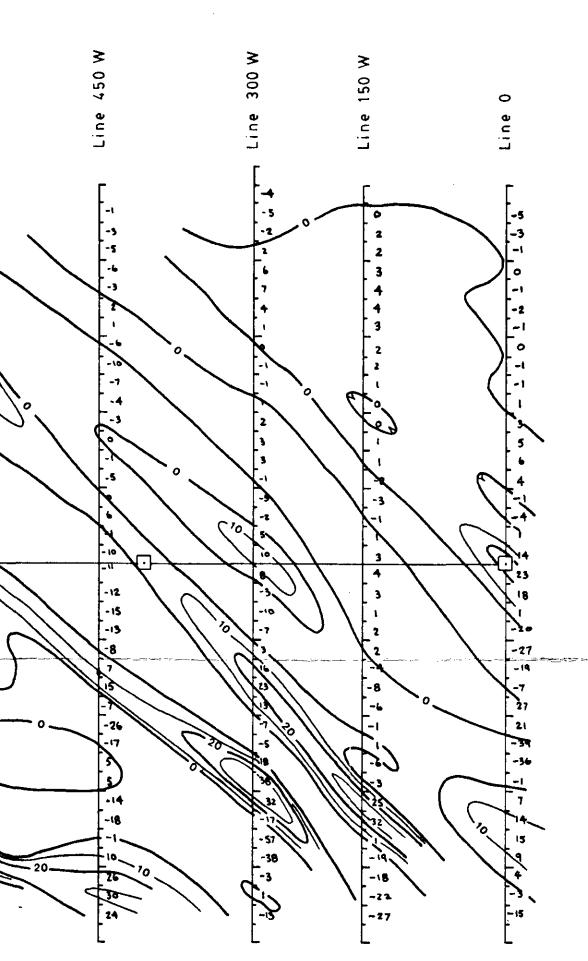

5.1 Introduction

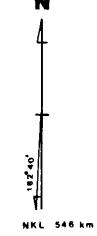

Ten man-days were spent in the collection of 223 soil Samples were collected and analysed at two different samples. times; September, 1981 and June 1982. Figure 7 shows the two areas sampled during these periods. The grid lines were nominal 150 m intervals and the sample stations spaced at were spaced every 50 m. This is a very coarse sampling pattern considering the relatively small size of the ore targets, but it was considered that the sampling program, of a reconnaissance nature, could delineate an area of exploration interest when the results were correlated with the geophysical Specifically, the objectives of the geochemical work work. were (1) to test for any verification of the inferred contact between the two units of concern, and (2) to examine for any

anomalous arsenic values near the contact area.

A sole element was analysed for economic reasons. Arsenic was selected because arsenopyrite is known to be a common occurrence in the pyritic replacement ore bodies in the area. In addition, arsenic makes a reliable indicator element for gold because of the marked coherence between gold and arsenic during both hypogene and supergene processes (Boyle, R.W., The Geochemistry of Gold and its Deposits, G.S.C. Bulletin 280, 1979).

5.2 Sampling Method

Figure 7 is a geochemical sample location map of the Whipsaw property. Conventional sampling practices were followed. Samples were collected in $3\frac{1}{2} \times 6$ " Kraft paper bags and their sites marked by flags. Soil sampling was preceeded by digging pits to $\frac{1}{2}$ m in depth to verify the local soil profile. The BF horizon was preferentially sampled if it was present. As only the minus 80 fraction was analysed coarse gravel and rock fragments were removed before bagging. Samples were air dried before sending to the laboratory.

Observations were recorded on field data cards, an example of which is shown in Appendix I. Appendix I also lists the soil samples and particulars on the sample sites.

5.3 Analytical Procedure

The samples were analysed by Chemex Labs Ltd., 212 Brooksbank Ave., North Vancouver, B.C. Conventional procedures, described in Appendix II, were followed on the minus 80 fraction.

5.4 Overburden Origin and Soil Profile

There are five major subdivisions of parent material over the claims area. These are, from north to south; (1) a well developed lateral moraine of boulder gravel on the south side of Willow River (Figure 5), (2) a narrow strip of even

Contoured Arsenic Values

Scale 1:5000 N.T.S. 93 H/4E Aug. 19/82 F1G. 7

textured silts and clays on the flat-lying area south of the moraine suggesting that there were times of relatively quiet water deposition related to backwaters of the ancestral Willow River or to glacial lakes in the valley, (3) moderately well sorted outwash sands and gravels which in general lie north of the location line and above the gentle topography of the fine sediments, (4) locally derived till, and (5) coarse angular talus of greenstone and amphibolite (Unit MPa) in the southwest corner of the map area.

It is estimated that the overburden thickness is 2-3 m in depth. This is based on observations of similar slopes to the southeast where road-cuts and trenches have exposed the bedrock.

Soil profiles are moderately well developed. The organic mat is generally 5-10 cm thick and underlain by a BF horizon 10-20 cm thick and a BM horizon of approximately the same thickness. In many places the BF horizon is not present and the BM horizon is the only distinct B horizon. The C horizon is encountered at depths of 30-50 cm.

5.5 Results

Figure 7 shows the analytical results for arsenic (ppm) in the soils sampled. Appendix III contains a histogram of the data set and Table 2 summarizes the geochemical statistics.

Table 2. Summary of Geochemical Statistics; Arsenic in Soil

No. Samples	Range	Mean	<u>Standard</u> Deviation	<u>Statistical</u> Threshold (1)
223	1-370	19.9	17.4	54.8

Note: - all values in ppm

sample with 370 ppm As deleted from calculations
(1) Mean + (2 standard deviations)

Isograds at 10, 20, 40, 80, 160, and 320 ppm As are shown in Figure 7. Soils with arsenic greater than the mean, 20 ppm,

occupy the central part of the sampling grid. Their distribution shows a crude northwest-southeast elongation. There are four sites with more than 80 ppm As. These also have a northwest-southeast alignment across the central part of the claims. There is a relatively large area of low arsenic soil content (less than 10 ppm) in the southwest corner of the claims.

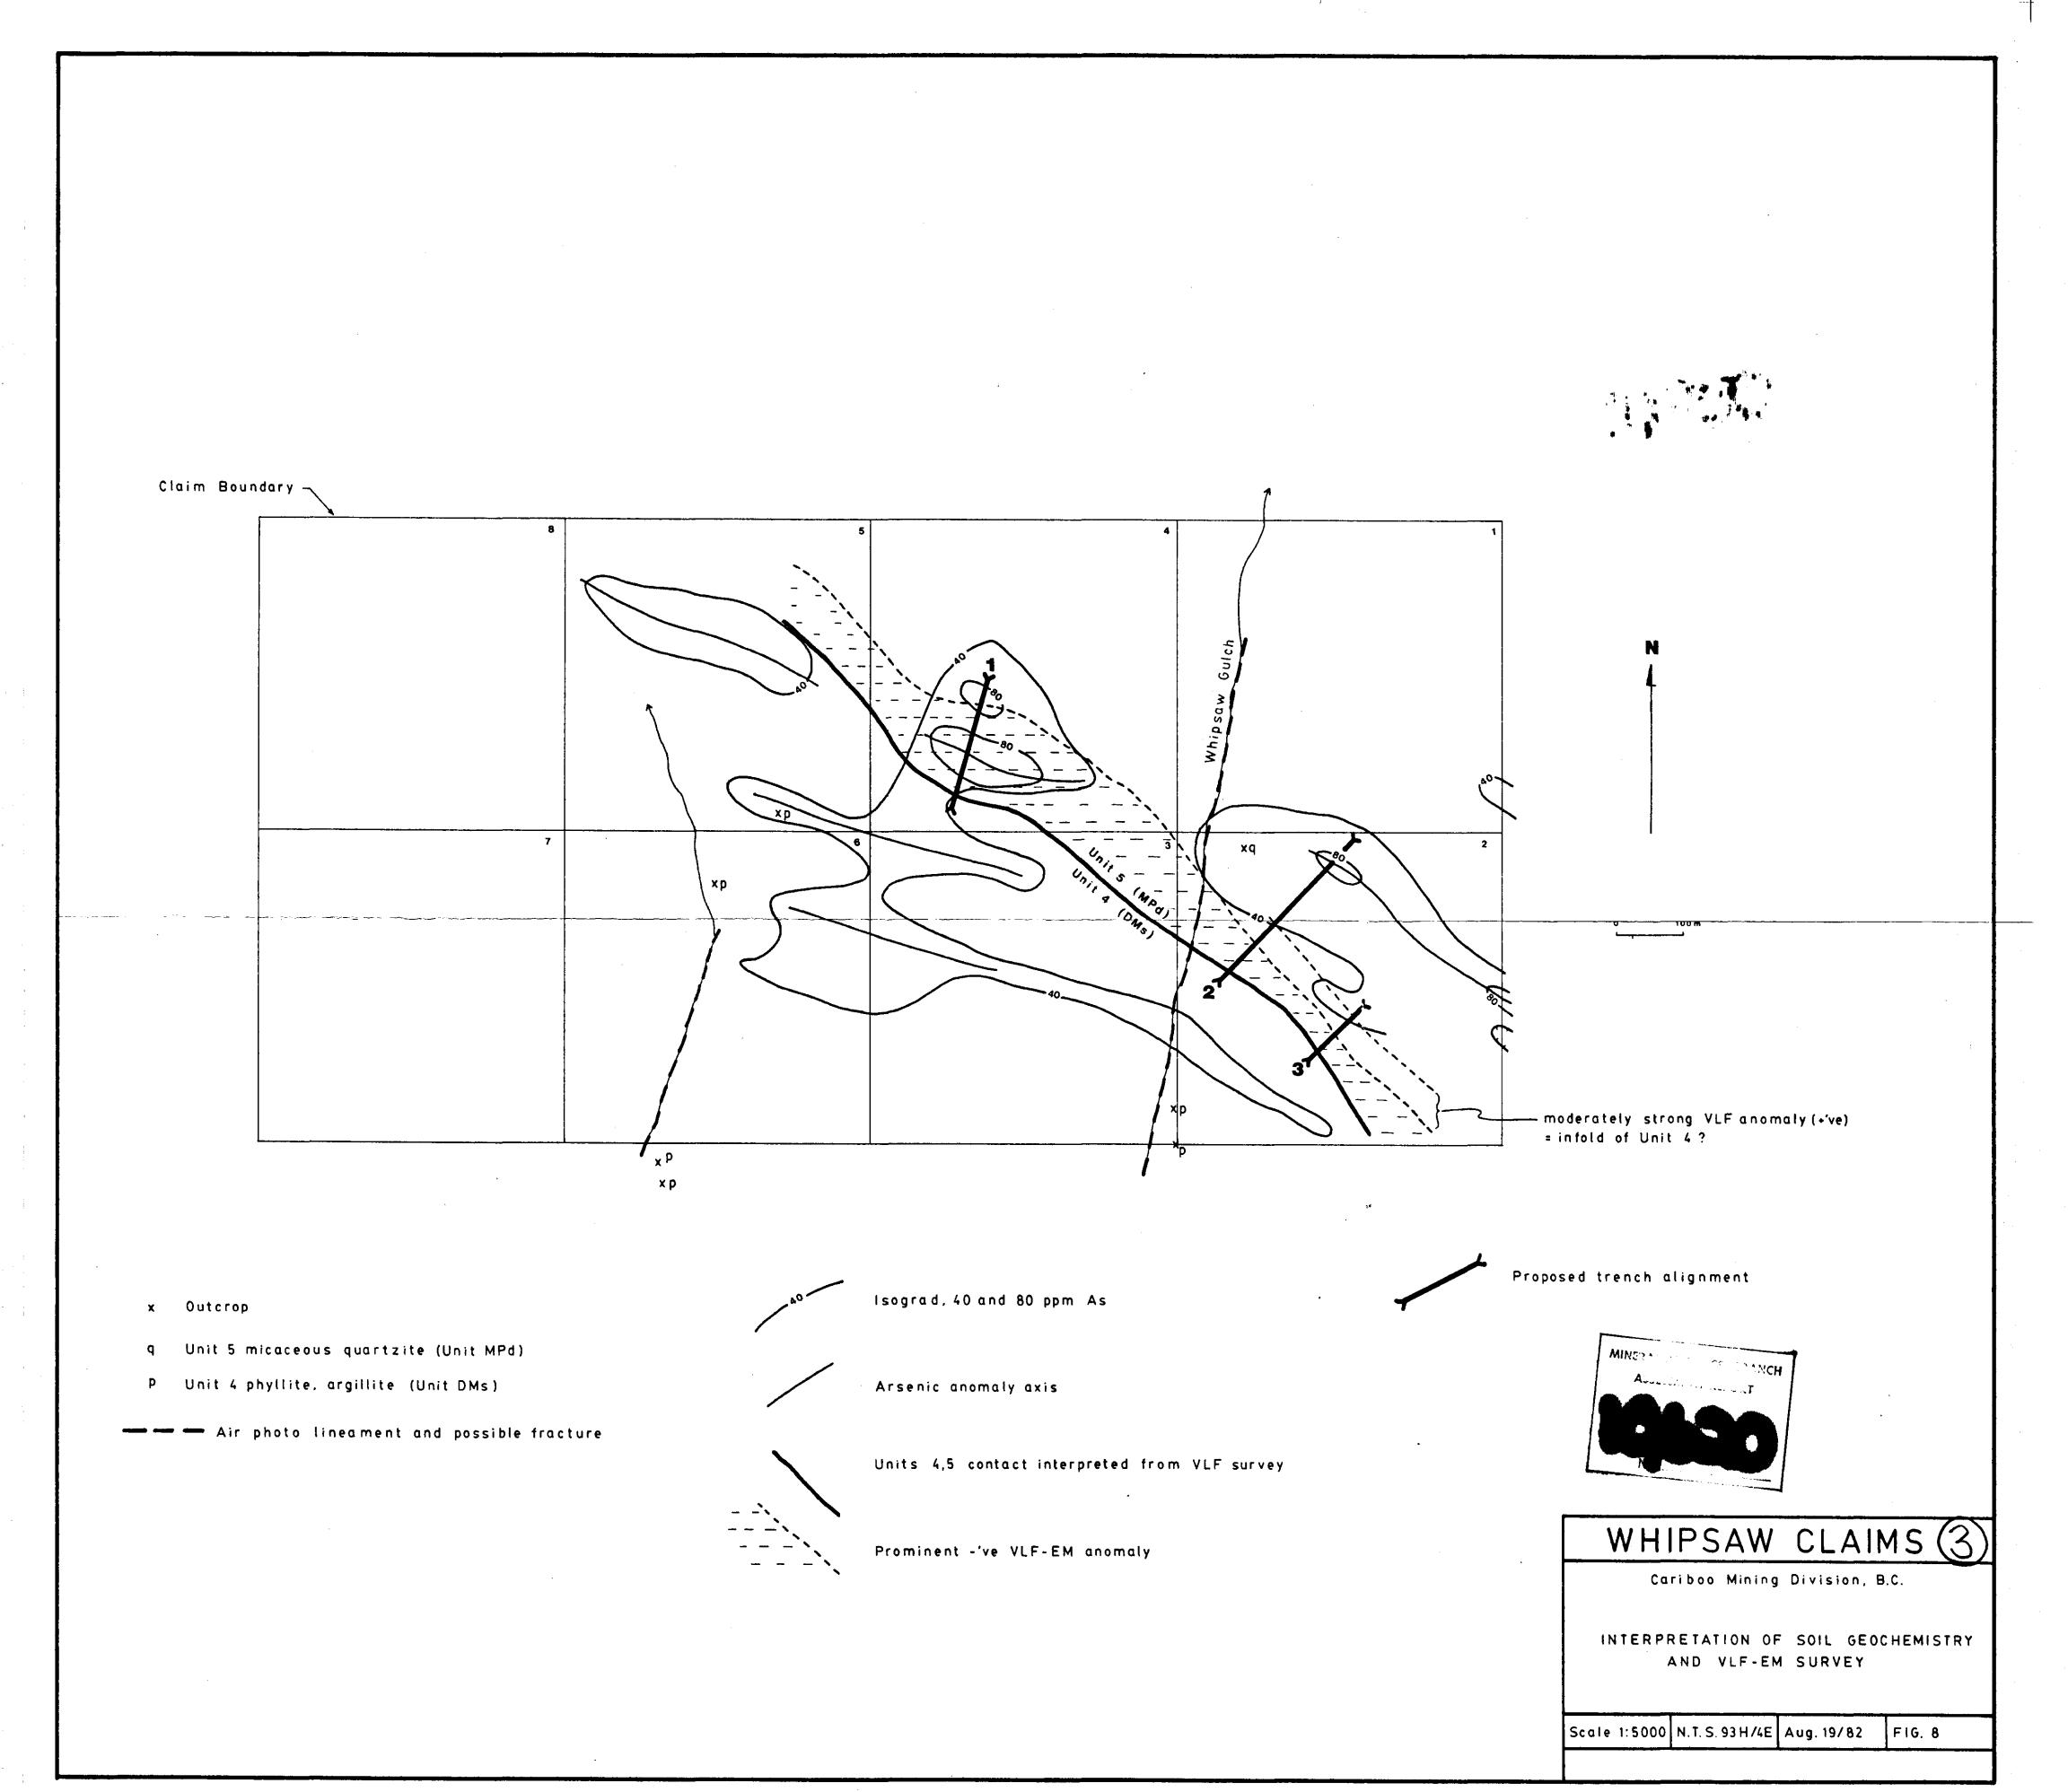

5.6 Discussion and Conclusions

The geochemical soil sampling on the Whipsaw claims indicates that there are soils with anomalous values of arsenic distributed across the central part of the claims and approximating the regional strike with a northwest trend. Figure 8 summarizes the location of soils with arsenic greater than 40 ppm (twice the mean) and 80 ppm. The general trend of the isograd axes is also shown.

The geochemical results give encouraging and supporting evidence for mineralization in conjunction with the geophysical interpretation. The geological contact between the black argillite and phyllite unit (Unit DMs or Unit 4) and the micaceous quartzite unit (Unit MPd or Unit 5) that was inferred from the VLF-Em survey is shown in Figure 8. The maximum arsenic values, specifically the four sites with arsenic more than 80 ppm, lie on the northeast side of this inferred contact. Recalling that the Baker Limestone Member, the host rock for pyritic replacement deposits which are intimately associated with arsenopyrite, is found within the micaceous quartzite unit near its contact with the argillite unit it is concluded that the arsenic anomalies are favorably situated.

6 RECOMMENDATIONS

It is recommended that trenches to bedrock be made along three alignments that intersect the inferred geological

contact in the neighbourhood of the arsenic anomalies. The proposed trench alignments are shown in Figure 8. Geological mapping and sampling of the bedrock in the proposed trenches is recommended.

8 ITEMIZED COST STATEMENT

The following expenses were incurred during the course of a geochemical soil survey, the completion of a VLF-EM16R survey and preparation of geochemical report on the Whipsaw Mineral Claims, 93H/4E, B.C., September 2nd, 1981 to August 15th, 1982.

APPENDIX II

Analytical Procedures

•

Geochemical Preparation and Analytical Procedure

Arsenic

The geochemical soil samples are dried at 80 C for a period of 12 to 14 hours. The dried sample is sieved to -80 mesh fraction through a nylon and stainless steel sieve.

A 1.0 gram sample is digested with a mixture of perchloric and nitric acid to strong fumes of perchloric acid. The digested solution is diluted to volume and mixed. An aliquot of the digest is acidified, reduced with Kl and mixed. A portion of the reduced solution is converted to arsine with NaBH₄ and the arsenic content determined using flameless atomic absorption.

The detection limit using a Techtron A.A. 5 atomic absorption unit is 1 ppm. A correction is made for background absorption.

APPENDIX III

Histogram of Sample Analyses
