1.0 INTRODUCTION

The Tchaikazan River project is located just west of the Taseko Lakes in south central British Columbia. This report covers work carried out on the SUN 1-14 claims which form part of the project area. Work performed on other claims will be covered under separate later submissions.

The property hosts a porphyry system with copper and molybdenum mineralization and peripheral gold and silver mineralization. The main area of interest occurs in the vicinity of the Hub area on the Tchaikazan River. The early work in the area was centered in this area. The SUN claims covered in this report were staked as a result of encouraging regional work in the area to the north of the original claim block.

1.1 LOCATION AND ACCESS

The property is 156 km from Williams Lake by air, but also can be reached by road using 4 wheel drive vehicles via Lee's Corners, and along the Lord River Mine development Road, a distance of some 270 km. The property can also be reached using float planes, by landing in Fishem Lake. Weekly servicing was obtained out of Williams Lake using both 4 wheel drive vehicles and helicopter support. A Bell Jet Ranger III on Term Charter was based out of the Fishem Lake Airstrip. The base camp was located on the south end of Fishem Lake adjacent to the Fishem Lake Airstrip.

The property is located within the Tyraughton Trough just adjacent to the Coast Plutonic Complex. Several promising prospects are located nearby; Fish Lake (Cu,Au) 35 km to the north, Poison Mountain (Cu), 75 km to the west, Lord River (Au) 8 km to the south east and Banner (Cu), 13 km east. Several other claim blocks exist in the area held by individuals and companies but are not at an advanced stage of exploration.

The claims covered by this report stretch from the RCAF Peak area to the north across the Yohetta Valley. The claims in the Yohetta Valley are partially accessible by road, however the greater portion is accessible only by helicopter. A network of pack horse trails exist in the area but these were not used. Early Mineral Exploration in the area was responsible for the clearing of these trails.

- 2 -

1.2 PHYSIOGRAPHY

The Taseko Lake area lies within the Coast Range Mountains. The area is cut by several U shaped valleys. The largest of which is the Taseko Lake Valley. It runs north-south and is one of the great U shaped valleys of the Cordilleran Interior System. This forms the eastern boundary of the property. Several other valleys run approximately North-North-easterly and are of glacial origin. The melt water from the many glaciers in the area is very cloudy and carries a lot of sediment; causing the Tchaikazan River and the Taseko Lake to be very cloudy and almost a turquoise color. The other streams and lakes with run off or ground water sources run clear.

The wide valleys and alpine terrain in the area show a transition from a well forested valley bottom to upper open alpine slopes to glacial ice fields. Elevations range from about 4350' to RCAF Peak at 9400'. The tree line lies between 6500' and 7000'.

- 3 -

1.3 PROPERTY HISTORY

Prospecting in the Taseko Lake area in 1945 led to the discovery of gold and silver mineralization in the vicinity of the Tchaikazan River. This work was carried out under the supervision of Dr. Harry Warren of the University of British Columbia. The showings occur within the Charlie group. The Charlie Group is located on "Tchaikazan River, Zelon Option" Map 81-075B. Limited sampling of these showings was undertaken and native gold, silver, and hissite, a gold telluride, were found to occur in the quartz vein. Further investigations were carried on during the winter of 1946-47. The mineralization was described in a paper written by Warren in the Royal Society Transactions (Warren, Harry V, 1947). The Charlie Group was optioned to Conwest for further development, however the option was allowed to lapse. No specific details regarding the work carried out is known.

In 1954 copper and molybdenum mineralization was located along the banks of the Tchaikazan River. Further trenching and sampling of the mineralization was also done. Harry Warren carried out a biogeochemical study of molybdenum on the property. (Warren, Harry V, 1965).

Between 1966 and 1967 Falconbridge carried out limited soil sampling, a magnetometer survey, shallow trenching and eight drill holes totalling 1250 feet. In 1968 Copper Range Exploration Co. built a road from Fishem Lake to the Cu-Mo showings and carried out further trenching and a further magnometer survey.

In 1969 Rio Tinto Exploration optioned the property and carried out detailed work on the property until 1973 when it dropped its option. Rio carried out a detailed soil sampling program around the hub area which revealed a significant Cu-Mo anomaly in the Hub area. Further trenching on this anomaly did not intersect sufficient mineralization to explain the soil anomaly (Troup A.C. and Peterson D.B., 1971). A magnetometer and induced polarization survey was

- 4 -

1.3 **PROPERTY HISTORY - (Continued)**

carried out and revealed an extensive area of increased chargeability over the property with a roughly circular chargeability depression in the centre of the grid area (Forminoff P.J., and Peterson D.B. 1971).

Rio Tinto carried out some 1501' in seven holes of diamond drilling but did not intersect sufficient mineralization to continue. In 1973 it dropped its option.

In 1979 Zelon Chemicals Ltd. (owned by John Hajek, a former Rio Tinto employee) option the property from Harry Warren. Zelon Chemicals carried out some limited prospecting and mapping in 1980. Late in 1980 Suncor optioned the property from Zelon Chemicals.

In 1981 a limited program of geological mapping, geochemical sampling and prospecting was carried out by a five man crew. A new grid was also cut with its origin at the Hub Trenchs. Additional acreage was acquired in the summer and fall of 1981 to bring the project area up to 13,000 hectares. Holdings as of January 1, 1981 are shown on Tchaikazan River Project Map 82-201. Work carried out on the project in 1981 is covered by Suncor Report #9046 (Hawkins, P.A., 1981) and #9047 (Hawkins, P.A., 1982). The majority of the work was confined to the Tchaikazan Valley. A limited amount of mapping was carried out elsewhere in the property.

Limited work was carried out in the Pond Creek area and near the Haho showing. Rock sampling in the area indicated the presence of several promising areas which warranted further followup and prospecting.

- 5 -

1.5 SPRING MAPPING PROGRAM

During the early part of the 1982 field season geological mapping was carried out over the SUN 1-14 mineral claims in the Taseko Lake area by a 10 man field crew. A staff listing is provided in the appendix. The mapping covered by this report took place between May 27 and July 15, 1982. The mapping was carried out under the supervision of Dave Dillon M.Sc. with the help of two Senior Assistants Karla Lange B.Sc. and Catherine Lawrence B.Sc. The project was under the overall supervision of Paul A. Hawkins, P.Eng. A number of junior field assistants also assisted in the mapping.

The mapping was conducted at a scale of 1:10,000 using blow-ups of Topographical maps as bases and with the use color airphotos flown by Western Remote Sensing in September 1981 for Suncor Inc. Traverses were carried out using pace and compass methods with helicopter set outs.

The area which was mapped covers 171 claim units or 4275 hectares. The claims form part of both the Yohetta Valley group and the RCAF Peak group which are shown on Drawing 82-157D and 82-157C.

- 6 -

1.6 ASSESSMENT WORK SUMMARY

The Assessment Work calculations were based on preliminary billings available at the time of the preparation of the Statements of Exploration and Development. A per manday field cost was arrived at, as shown in the appendix, and this was applied to each claim depending on the actual number of mandays spent on the claim. A total of 66.5 mandays were spent mapping on the claims. An average crew salary figure was used in the calculation as obtained in the appendix.

Certain costs were transferred to other claims within their claim group. No charges were made for assays or geochemical analysis which were not completed at the time of the preparation of the statements. This data will be filed as a separate report.

- 7 -

2.0 GENERAL GEOLOGY

The Tchaikazan River property is located within the Tyaughton Trough of the Intermontaine Belt. It is just adjacent to the eastern margin of the Coast Plutonic Complex. Locally the property appears to be part NW trending belt of Cretaceous sediments and volcanics intruded several recent felsic instrusive centres of Late Cretaceous or early Tertiary age.

The Taseko Lake Area was mapped by H.W. Tipper (Tipper, H.W., 1963) and updated again in 1978 (Tipper, H.W., 1978). The sedimentary rocks are discussed in GSC Paper 67-54 (Jeletzky, J.A. and Tipper, H.W., 1968). The area has never been properly mapped with respect to the volcanics and the instrusive of the area. The main rocks of interest during the mapping were the sediments. The GSC mapping of the volcanic rocks in the area is not reliable on a detailed scale.

The Cretaceous sediments and volcanics of the Taseko Lake area are probably part of the Taylor Creek Group. No attempt was made to correlate rock units by field staff. Sedimentary rocks in the project area include: shale, conglomerates, Arkose, Argillates, mudstones and sandstone. Volcanic and pyroclastic rocks in the area were: andesites, basalts, greywache, tuff and agglomerates. Instrusive rocks of the area are: feldspar Porphyry, Quartz feldspar porphyry, granodiorite, diorite, pegmatite, felsite and lamprophyre dikes. The amount of alteration present sometimes hampers the field determination or rock type.

- 8 -

2.1 ROCK UNITS

Rock unit names were developed from early field mapping during the first part of the 1982 field season. Several modifications will likely be required before a satisfactory set of units and correlations can be made. The severe alteration in some areas hampered field determination. The gradations of some of the volcanics into sediments was also a major problem. A simplified table of units is provided however a more detailed discussion of units follows.

BLACK SHALE (UNIT 1)

- black, fine grained, often exhibiting laminar banding fissile.
- slately cleavage
- invariably shows rusting
- commonly found interbedded with argillite
- weathers to black blocky material
- occassional disseminated pyrite

QUARTZ PEBBLE CONGLOMERATE (UNIT 2a)

- generally buff to greenish and containing a fine matrix (less than 10%) often limonitic.
- outcrops seen on north side of Yohetta Valley are typical.

- tan to pinkish brown also greenish to greyish often lithic fragments generally medium grained but poorly sorted.
- well bedded and resistant unit.
- best outcrop exposure occurs in the lower half of airstrip creek.

CONGLOMERATE (UNIT 2c)

- new unit to include conglomerates from 3c and 4b
- largely made up of lithic fragments of older adjacent units usually volcanics
- medium to very coarsely grained

BLACK-GREY BASALTS (UNIT 3a)

- fine grained to aphanitic
- vesicular, often containing olivine or pseudomorphs after olivine, also amygdular varieties present.
- basaltic flows
- sometimes magnetic
- vary from black to grey to dark green in color
- occasionaly with pyroclastic fragments or lithic fragments from the edge of flows
- amphiboles often visible.

DARK PURPLE - BASALTS (UNIT 3b)

- fine to medium grained
- purple, often vesicular and porphyritic pnenocrysts and generally plagioclase
- may contain lithic fragments
- often grades into a dark green andesite-basalt
- vary from denser darker, very well indurated rocks to less dense poorly indurated rock which is normally highly weathered, but still retains its characteristic volcanic appearance.

PURPLE-MAUVE GREYWACKE (UNIT 3c)

- very fine grained to very coarse grained
- color varies formed dark grey to green to brownish to light grey and green to mauve to deep purple
- sometimes conglomeratic
- poorly sorted and polymictic often exhibiting graded bedding
- unit may also include bictic often exhibiting graded and lapille tuffs
- clastics were subangular to subrounded
- no preformed orientation in clasts
- varied from poorly to well endurated
- in many cases it was difficult to distinguish from greywacke and tuffs
- purple and green tinted soils are commonly below or covering such this unit and is likely the weathering product.

- 16 -

ARGILLITES (UNIT 3d)

- massive bedded to banded fine grained sediments periodically exhibiting festoor bedding, and flame structures (This unit may include some tuffs) color is variable from black through blacks to browns to light green.)
- commonly interbedded with black shale

- commonly massive or porphyritic
- with small lithic fragments
- dark colored
- commonly vesicular with feldspars and pyribale
- disseminated pyrite sometimes present
- not always clear if unit is flow or not
- amygdules range in size from a few mm to several cm in length
- characteristically ellysoid and elongate in the direction of flow
- flows often cross cut by quartz carbonate veins
- veining has undergone chlorite alteration in some areas.

GREEN-GREY-BROWN GREYWACKE (UNIT 4b)

- similar to Unit 3c
- in some areas conglomeratic
- green to purple to grey coarse grained with a fine grained matrix
- fragments may be chert, unknown lithic fragments, purple basalt, greenish basalt/andesite, or rounded feldspar grains
- several types may exist

SANDSTONE (UNIT 4c)

- medium to coarse grained and well sorted
- clast composition is varied and impure
- A siltly-clayey matrix is common but not always present
- light grey to brown in color usually massive,
 some beds visiable on north side of Yohetta Valley

PYROCLASTICS (VOLCANICLASTICS) (UNIT 4d)

- volcanic clastics tuffs, agglomerates
- clastics generally sub angular to angular
- tuffs appear sometimes to be welded
- generally characterized clasts with chill rims in a fine grained matrix
- tuffs were low color index, aphanitic, commonly mineralized with disseminated pyrite
- agglomerates were rare

PORPHYRITIC HORNBLENDE ANDESITE (UNIT 5a)

- a mesocratic olive green groundmass, contains amphibole laths. The groundmass is fine grained to aphenitic.
- some amphibole crystals up to 1 cm in length
- randomly oriented

GREEN TO VERY LIGHT GREY ANDESITES (UNIT 5b)

mesocratic to leucocratic and porphyritic.
 Phenocrysts and microphenocrysts are hornblende
 and white feldspar in a green groundmass.

FELSITES (UNIT 6)

- grey to white to buff aphenitic rock exhibiting concoidal fracture.
- fine grained to aphanitic

QUARTZ-FELDSPAR PORPHYRY (UNIT 6a)

-	mesocratic to melanocratic rock phenocrysts quartz, white feldspar (1 cm long), and hornblende
-	matrix varies from fine to coarse grained
-	ratio between felsic and mafic varies
-	phenocrysts reach up to 5 cm in size but average 4 mm
-	commonly carries pyrite and occasional cholcopyrite
-	usually exhibits argillitic alteration
	pyrite and magnetite common

.

·--- - -

FELDSPAR PORPHYRY (UNIT 6b)

- there are several textural variations
- crowded hornblende feldspar porphyry dominated
 by phenocrysts of white feldspar and hornblende
- sparse hornblende porphyry dominated by aphanitic
 groundmass with white feldspars and hornblende
- porphyry breccia essentially sparse porphyry with fragments of country rocks
- phenocrysts sizes: feldspar (12 mm), hornblende
 (3 mm)
- mineralogical variation involves replacement of hornblende by biotite in the periphery of the hub stock, as well as zonation of sulphides from molybdenite and chalocpyrite disseminations in the inner zone to increaseing pyrite outward

GRANODIORITE, GRANITE, PEGAMITITE (UNIT 6c)

- granodiorite medium grained pinkish beige rock containing white and pink feldspars (ratio 9:1), quartz and biotite
- granite medium grained pinkish beige rock containing white and pink feldspars (ratio 6:4), quartz and biotite
- pegmatite veins (rare) very coarse grained leucocrastic rock containing micorcline and quartz

LAMPROPHYRE DIKES (UNIT 7)

 melancratic green to dark grey to black porphyritic rock containing phenocrysts of hornblende (?) and rare feldspar TCHAIKAZAN RIVER PROJECT

TABLE OF ROCK UNITS

Igneous Extrusives

Pyroclastics

Tuffs:	light through	dark grey,	aphanitic to
crystall	ine, sometime:	s clastic.	
Agglomer	ates, usually	red or gree	en.

Volcaniclastics Basaltic and andesitic flows are commonly clasticvolcanic breccias occur locally.

Flows Andesite, grey through green, aphanitic to porphyritic; extremely porphyritic may be igneous intrusive. Phenocryst usually hornblende and feldspar. Basalt, grey, brown, through to shades of purple. Purple color due to local concentrations of hematite (?). Commonly porphyritic, as for andesite; also vesicular and amygdaloidal.

Igneous Intrusives

Lamprophyres Basic, porphyritic to aphanitic dikes cross-cut stratigraphy locally.

Porphyries Occuring as dikes, stocks, and sills. Feldspar porphyry, green-grey matrix with well formed feldspar phenocrysts, usually plagioclace, up to 1 cm across. Hornblende is a common accessory phenocryst. Quartz feldspar porphyry: same as feldspar porphyry but containing an appreciable amount of quartz: 10-20%. Felsites: light colored, fine-grained to aphanitic igneous rock. Quartz-eye felsites occur when the felsite contains aupen-shaped quartz phenocrysts.

Sedimentary rocks

Shale

Sandstones

Greywacke

Black, aphanitic, fissile and friable, low resistance to weathering.

Argillaceous sediments Usually interbedded shales, mudstones, siltstones.

Include classically formed sandstone as well as some slightly impure varieties.

Dark grey, brown, also purple. Sandstone with large detrital quartz and feldspar phenocrysts. Fragments angular. Exhibits graded bedding locally. Includes some conglomeritic sections.

Conglomerates Green through brown through purple. Typically poorly consolidated. Complete range in clast size and composition. Clast shape mainly well rounded. Quartz pebble conglomerates found locally.

2.2 ECONOMIC GEOLOGY

A number of new showings have been located in the SUN 1-14 mineral claims. They all show copper mineralization and are all fracture related. How they locally relate to a porphyry model has not yet been determined. The showings are located on drawing 82-204, New Showing Location 1982 - Tchaikazan River Project.

The following discussion is based on field observations and preliminary assay data which will be submitted later.

The Barndoor showing is located SUN-5 on a ridge on west side of Pond Creek on the south side of Yohetta Valley. The showing is a spotty occurrance of malachite in a highly fractured dark grey basalt. The basalt is also highly altered in some spots to largely clay minerals. The mineralization was of limited extent. Further stripping of outcrop combined with detailed mapping is required.

The Haho showing located in SUN-14 and Helena claims returned good values in copper and silver (Hawkins, P.A., 1982). Further work was undertaken in the area and several other showings were found. This area is now called Ravioli Ridge and extends to the east and south east of Haho. These showings carry malachite and chalcopyrite. They appear to be related to quartz carbonate veining. The Ravioli showings occur in outcrops while in the case of Haho, no outcrop source for the mineralized boulders has yet been found. The mineralized boulders at the Haho showing have now been extended to cover an area 20 x 40 meters.

A number of showings have been found on the unmarked peak just west of Fishem Lake. The Peak at 7724' stands out as it is almost isolated from other peaks in the area. The showings occur on the ridge running south east from the peak. Malachite with

2.2 ECONOMIC GEOLOGY - (Continued)

minor azurite occur with disseminated chalcopyrite and rare pyrite. The malachite and azurite appear associated with minor folding in the sediments in which they occur. They also appear as fracture coatings in the intrusive rocks in adjacent areas. The rocks are highly weathered and previously present sulphides appear to have been leached out.

Fresher rock samples may yield better results. Further prospecting and detailed mapping is required. The showings may be related to the intrusive rocks which appear to make up the core of the mountain.

Several mineral showings exist on a ridge west of Pond Creek. The ridge on which the showings occur have been named "Amazon Ridge". The Amazon ridge area comprises 3 mineral claims SUN-5, 12 and 14. Mineralization consists of malachite, azurite, chrysocolla, native copper and native silver.

The rocks in the northern part of the ridge are composed of porphyritic andesites while the southern portion of the ridge is composed mainly of clastic sediments, commonly hematized. Mineralization is not confined to one rock unit but usually occurs in fractures and cross cutting quartz carbonate veins. Malachite and azurite were also found in a feldspar porphyry associated with jointing surfaces, which may be related to stockwork mineralization.

Native copper, malachite, azurite, chalcopyrite, chrysocolla and possible native silver were located on the west side of Amazon ridge. Several fracture related zones carry impressive copper oxides. One such zone called the Ring showing carries a narrow vein about 1 cm wide of metal copper and possible silver. Further detailed mapping and prospecting is required.

Another area of minor interest is the Catwalk area in SUN-1 and Echo-5. Several Quartz-carbonate veins exist in areas of known

- 31 -

2.2 ECONOMIC GEOLOGY - (Continued)

gossen zones. No sulphides were seen but it was not possible to get an unweathered sample. Further examination is required.

In summary, the area has a number of new Cu, Ag showing which are a definite indication of the high mineral potential of the area. All the showings are fracture related and may fit into a porphyry copper model. The area however requires much more work.

3.0 CONCLUSIONS

The SUN 1-14 claims host several recently discovered showings. Further more detailed work is required to fully evaluate these showings. Additional regional geological mapping is also required. The completion of the chemical analysis of rocks and soils will also greatly assist in the evaluation.

It is apparent from past work (Hawkins, P.A., 1982) and outcrop examinations during mapping that significant copper, gold and silver mineralization exists within the area covered by report and warrants additional, more detailed examination.

Paul & Hawkin

3.1 FURTHER WORK

Regional mapping should be continued with additional prospecting in the area. Detailed mapping should be undertaken at the Barndoor, Haho, Catwalk, Ring and Pond Creek areas. Geophysical surveys such as Magnetometer and VLF-EM should be carried out at Barndoor, Haho, Ring and Pond Creek areas. Better control should also be established in all areas. Further rock sampling would better define these showings.

Author's Qualifications

Paul Alan Hawkins P. Eng. B.Sc. (Eng) 2105, 920 - 9th Avenue S.W. CALGARY, Alberta T2P 2T9

Registered Professional Engineer, Province of Alberta

B.Sc (Eng) Queen's University 1977 Geological Engineering (Mineral Resources)

Work History

.

May 1981 - Present	Suncor Inc.	Project Geologist
May 1978 - March 1981	Pan Ocean Oil Ltd.	Project Geologist
Feb. 1978 - April 1978	Gulf Minerals	Drill Geologist
May 1977 - Jan. 1978	Asamera Oil	Junior Geologist
July 1976 - Dec. 1976	Urangessellschaft	Senior Assistant
May 1976 - July 1976	Hollinger Mines	Drill Geologist
May 1975 - Sept. 1975	HBOG Mining	Field Assistant
May 1974 - Sept. 1974	Duval Corp.	Field Assistant

FIELD STAFF LIST

1. David Dillon M.Sc. (Geology) Brock University 1982 B.Sc. (Geology) University of Toronto 1979 2. Catherine Lawerence B.Sc. (Geology) University of Western Ontario 1982 3. Karla Lange B.Sc. (Geology) University of British Columbia 1982 4. Jacqui Rublee 2nd year geology student, University of British Columbia 5. Kimberly Russell 2nd year geology student, Sir Sandford Fleming College 6. Richard Laing B.Sc. (Biology) University of Calgary 1st year geology student, University of Calgary 7. Steve Barnhart 2nd year geology student, Unveristy of Waterloo 8. Jim Boyd 2nd year geology student, McMaster Unversity 9. Reno Pressacco Graduate geological technician, Cambriam College 1982 10. Gerald Lalonde Cook 11. Derek Armstrong B.Sc. (Geology) University of Waterloo 1982 12. Derek Newman 3rd year geology student, Memorial University

13. John Mirynech

1st year geology student, University of Western Ontario 14. Mark Ho

2nd year geology student, University of Waterloo

15. Don Sabo

lst year geology student, University of Saskatchewan

16. Roy Lush

Cook

17. Ernst Maas

Helicopter Pilot

18. Cynthia Bonthoux

Replacement Cook
