Summary

Following a program of reconnaissance geochemical sampling and prospecting, the RANGE 1-2 claims were acquired in October, 1981. The claims are centered on a base metal-silver soil anomaly.

In 1982, a program of linecutting, stream and soil sampling, plus geological mapping, was performed to evaluate the reconnaissance anomaly. Several base metal and silver anomalies were discovered, and a limited bulldozer trenching program was carried out. Results of the trenching are not conclusive, and further work is planned. RANGE 3, 4 were staked at the end of the 1982 season.

The RANGE claims are a 50-50 Joint Venture of BP Minerals and The Saskatchewan Mining Development Corporation, with BP Minerals Limited as operator. Geological mapping only was done by Bob Cann, an SMDC staff geologist.

Recommendations

- 1) Bulldozer trenching and sampling of the copper-molybdenum-zinc anomaly on L2+00S from 0+50W to 3+00W.
- 2) Fill in geochemical soil sampling from L15S to L20S from the baseline to 4+00W. This will detail the southerly extension of the breccia dike zone.
- 3) Reconnaissance geochemical and soil sampling of RANGE 4, which was staked to the south of RANGE 2 to cover any possible southern extension of the breccia zone.
- 4) Geological mapping of RANGE 4 at a 200 metre line spacing.

CAPOOSE LAKE PROJECT - GEOCHEMICAL & GEOLOGICAL SURVEY

Introduction

The Nechako Plateau, southwest of Prince George has been until recently, a relatively unexplored part of British Columbia because of limited access. Riocanex conducted a regional lake sediment reconnaissance of the Nechako Plateau during the period 1969 to 1970. Those data were published by Hoffman and Fletcher (1976) and Hoffman (1976). Restricted access in 1976 continued to limit exploration activity. Since that time, Plateau Mills (B.C. Timber) of Vanderhoof has constructed the 160 km long Kluskus Forestry access road. Logging operations have placed many anomalies within walking distance of the road and an active road building program is underway which will provide excellent road access to much of Nechako Plateau in the next five years.

Schroeder (1981) described the geology of five widely separated precious metal deposits or significant precious metal occurrences within the central interior of British Columbia. One of these occurrences lies on the Fawnie Range east of Capoose Lake. The location of the mineralization (Schroeder, personal communication, 1982) lies under the largest soil lead and zinc anomaly defined by Hoffman and Fletcher (1981). Other soil lead and zinc anomalies remained on open ground.

The Nechako Plateau reconnaissance was initiated to assess lake sediment anomalies assorted with volcanic terrain, in a preliminary fashion, using soil and drainage geochemistry, geological mapping, and prospecting methods. Anomalous areas are underlain by either Takla or Hazelton rocks. The geological target type comprises a volcanogenic massive sulphide or precious metal deposit modelled after the Capoose Lake, Equity Silver Mine or Kuroko deposit types.

The Capoose Lake Project was initiated in 1982 to evaluate previously known lake sediment and soil geochemical anomalies located near the Granges Bulk silver prospect on Fawnie Dome. Following a reconnaissance geochemical sampling and geological prospecting program, the RANGE claims were staked in August 1981. These claims covered land over a prominent geochemical soil anomaly having element associations and levels (excepting silver) comparable to those at the Granges deposit.

In 1982, a previously located soil anomaly was investigated in detail by means of a geochemical sampling grid. Detailed soil sampling confirmed the anomaly and a limited trenching program was performed to expose the anomalous zone.

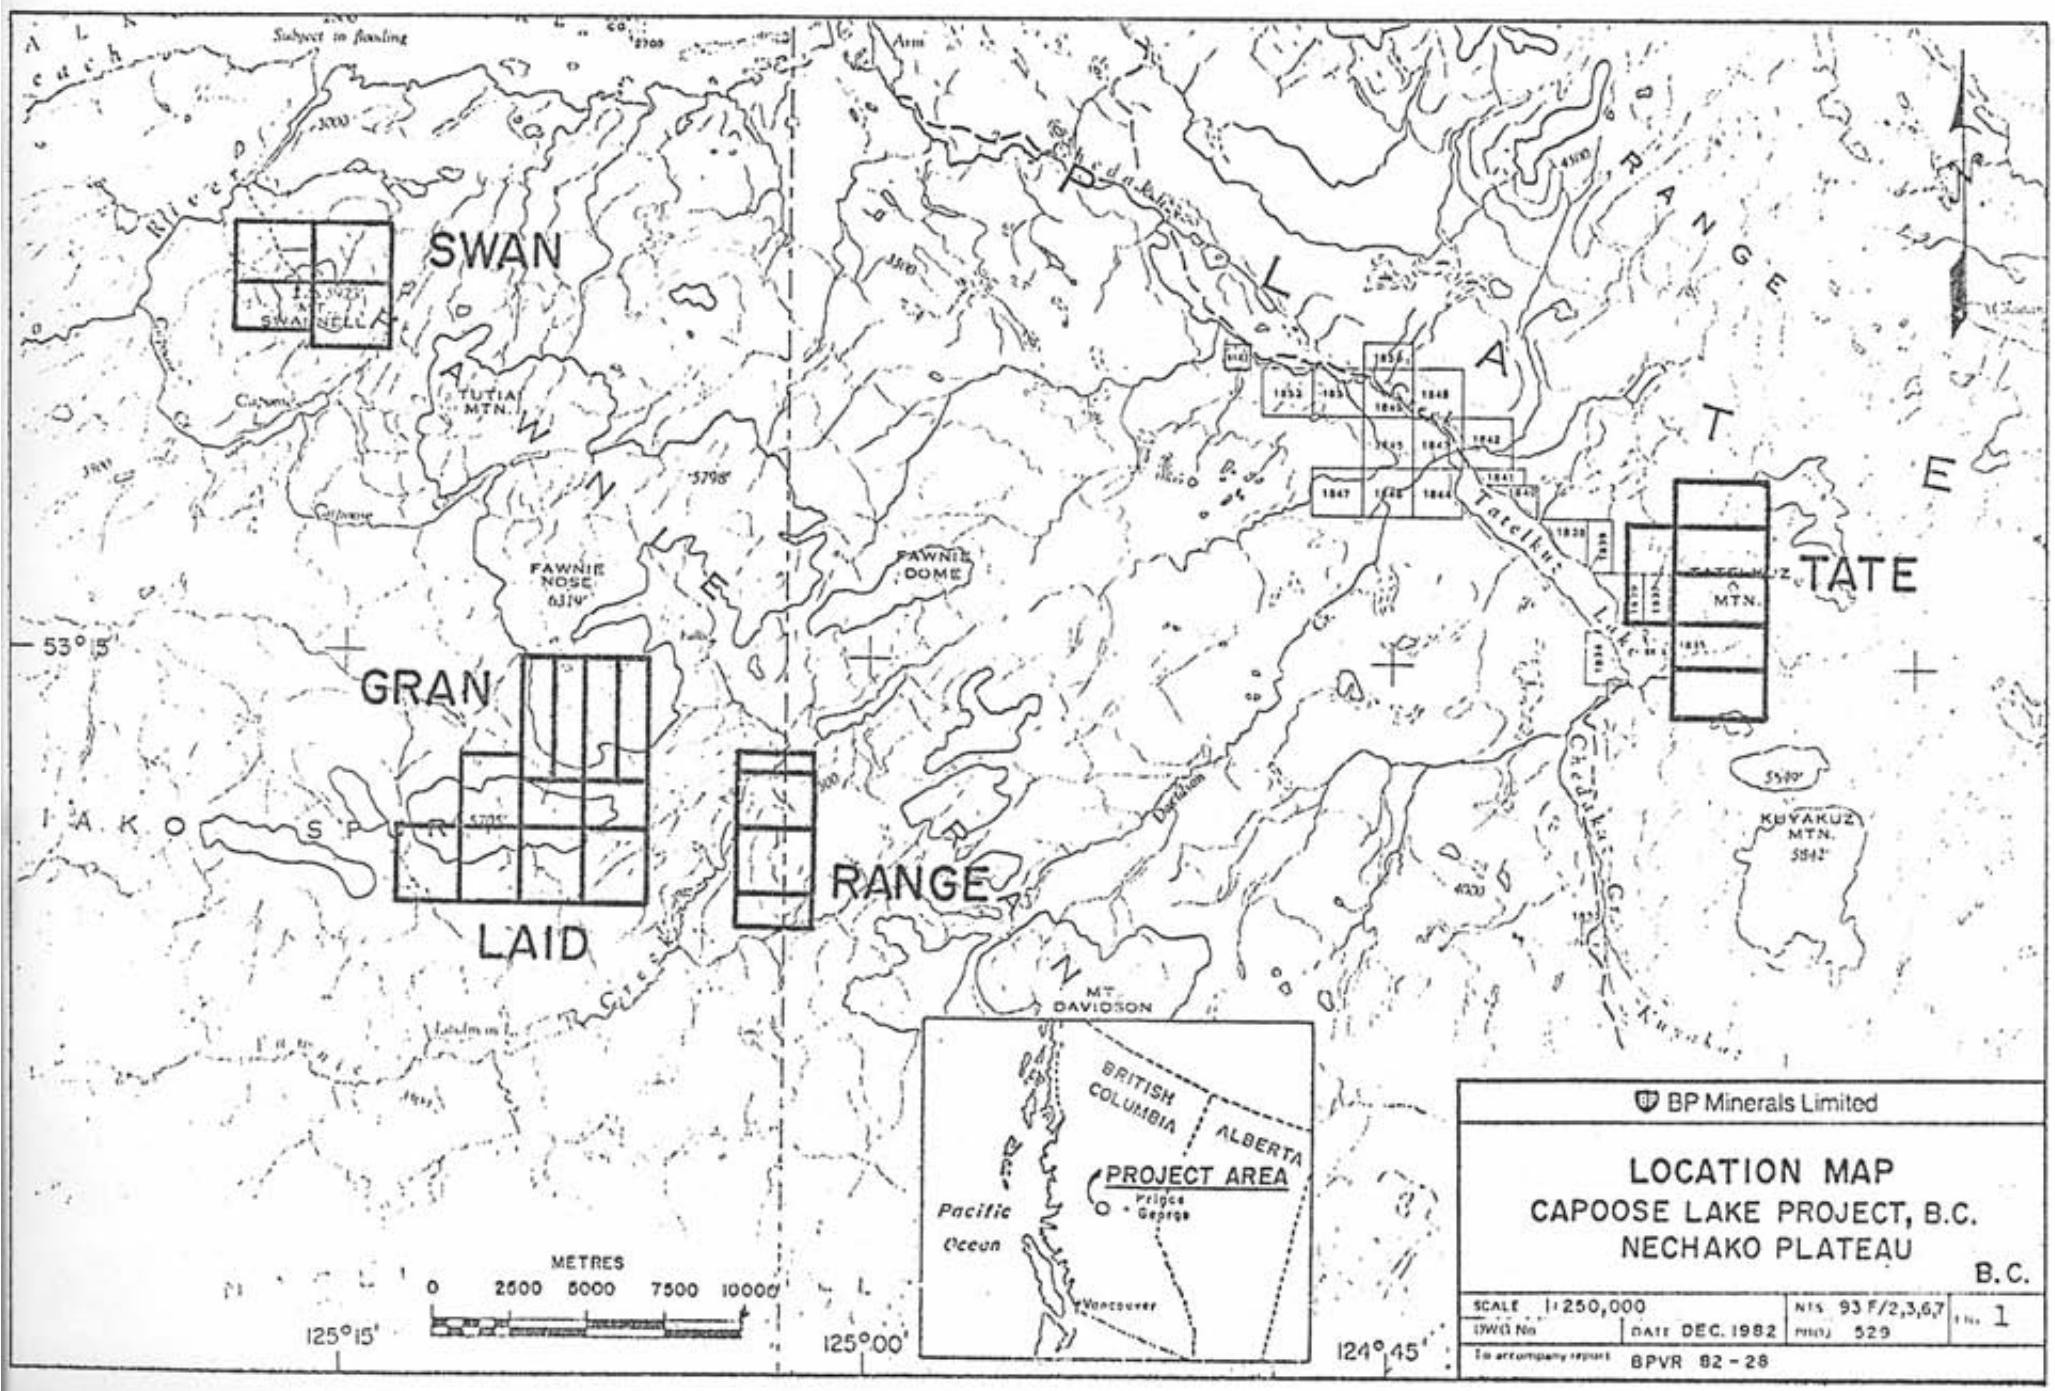

Location and Access (Figure 1)

The RANGE claims are located in the Fawnie Mountain Range, NTS Map Sheet 93F/3, 109 kilometers southwest of Vanderhoof, B.C. The area is accessed by the Kluskus Forestry Road of B.C. Timber Ltd., which begins at their Engen Mill, located 19 km west of Vanderhoof. From Engen, the forestry road is followed southwest 146 km. From this point a logging access road is followed upslope in a southerly direction for 1 km, at which point the centre of the claim group is accessed.

Claim Status and Ownership (Figure 2)

The RANGE Claims are owned wholly by BP Minerals Limited. The RANGE Claims consist of 40 contiguous units in two claim blocks. The recording dates are tabulated below:

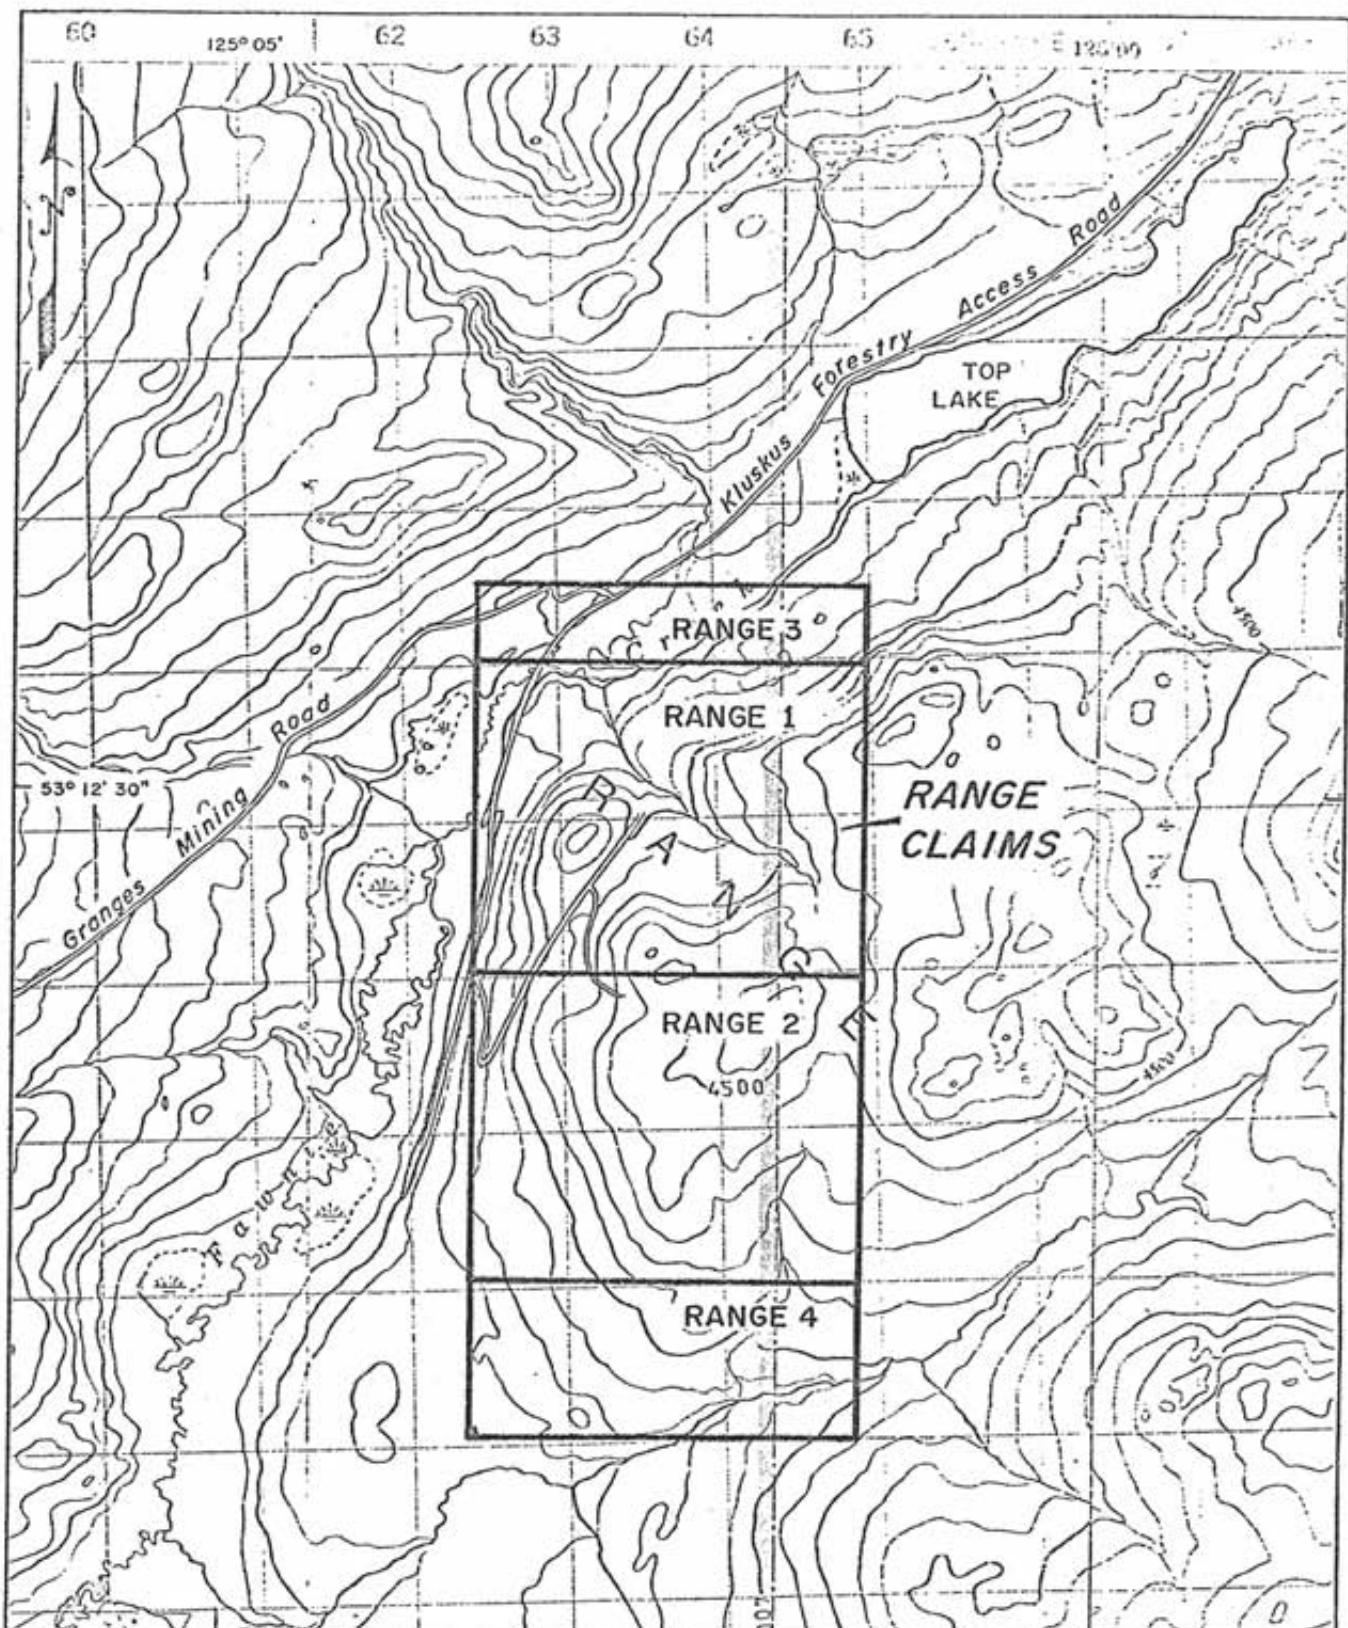

<u>Claim Name</u>	<u>Units</u>	<u>Record #</u>	<u>Recording Date</u>	<u>Expiry Date</u>

Summary of WorkPrevious Work on the Property

As far as can be ascertained from field evidence and available reports, no previous exploration has taken place on the Claim Group. The centre of the RANGE 1, 2 Claims is a logging clearing, crossed by logging access trails.

Summary of Work - 1982

A program of linecutting, geochemical grid sampling, geological mapping and bulldozer trenching was performed on the RANGE 1, 2 Claims during the period June 13 - September 15, 1982. During this period, a crew of two to four samplers, one geologist and four linecutters worked on the grid for varying periods of time.

RANGE Grid (See Figure 4A)

A north south baseline was transited in a magnetic north south direction for a distance of 4100 m. This baseline was tied into Fawnie Creek and the Kluskus Forestry access road. East-west tie lines were cut, blazed, and chained at L6+00N and L33+00S west about 800 m to the Kluskus road and east 1600 m to the RANGE Claim boundary. North south tie lines were then cut, blazed, and chained from L6+00N at 8+00W and 16+00E for a distance of 2300 m south.

Using this framework, 26 east-west soil geochem lines were run by compass and topofil chain, flagged, blazed from baseline to tie line, then sampled at 100 metre intervals. Additional detail sampling was done in August at 50 m intervals in anomalous areas. A total of 77.3 km of line were cut, blazed, flagged and chained.

Geochemical Sampling

Soil samples were taken at 100 metre intervals along the east-west soil lines. Stream samples were taken when streams were crossed on lines, and duplicate samples taken every 30 sample sites. The 100 metre line spacing was maintained from L6+00N to L16+00S, then a 300 metre line spacing was adopted for the rest of the grid. A total of 731 soil and stream sediment samples were collected. The results of the sampling are presented in the geochemical section of this report.

Geological Mapping

The RANGE 1, 2 Claims were mapped by Bob Cann, a SMDC geologist, during the period June 21 - 30 and July 17-19, 1982 at a scale of 1:5,000, using the soil grid, a 1:5,000 topographic base map, and a 1:5,000 airphoto mosaic as control. Chip samples were collected from mineralized outcrops and representative samples taken of each lithology.

Geology

Regional Geology

Regional geology is shown in pocket. Because of inaccessibility and extensive drift cover, little regional work has been done in this area. The most recent publication covering the region is GSC Memoir 324 (Tipper, 1963).

Oldest rocks in the area are Lower Jurassic andesitic volcanic rocks and minor interbedded argillite which are assigned to the lower part of the Hazelton Group in recent compilation maps (GSC Maps 1424A, 1505A). Previously these rocks had been assigned to the Takla Group by Tipper (1963). Conformably overlying these rocks is a sequence of Middle Jurassic interbedded greywacke, shales, pyroclastic rocks, and rhyolite to andesite flows which also are assigned to the Hazelton Group. The Capoose deposit is hosted by rhyolite and argillite belonging to this sequence.

Intruding the Hazelton rocks are Cetaceous and/or Tertiary stocks and botholiths of granite to diorite composition. Porphyry copper and molybdenum mineralization is locally associated with these rocks.

Upper Cretaceous or Tertiary rhyolite, dacite and trachyte flow and tuffs belonging to the Ootsa Lake Group unconformably overlie the above units.

Miocene basalt flows occur locally in the vicinity of Natalkuz Lake.

Local Geology

The Range claims were mapped during the periods June 21-30 and July 17-19, 1982 at a scale of 1:5,000, using the soil geochemistry grid, topographic base map and a 1:5,000 airphoto mosaic for control. Chip samples were collected from mineralized outcrops and representative samples were taken of each lithology.

In general terms the claims are underlain by Lower Jurassic sedimentary package which is overlain by two distinct volcanic units (Fig.). The sedimentary package can be subdivided into a lower unit consisting dominantly of shale, siltstone and tuff, and an upper unit consisting mainly of coarser clastic rocks. The oldest volcanic unit is andesitic in composition and probably Lower Jurassic in age while the younger volcanic unit is mainly felsic and probably Tertiary in age. All mineralization and geochemical anomalies discovered to date are found within the sedimentary units.

Unit 1, the stratigraphically lowest sedimentary unit consists predominantly of thinly bedded dark grey siliceous shale, siltstone and tuff. Fine-grained tuffaceous sandstone and arkosic sandstone with a deceptive igneous texture occur interbedded with the siltstones and tuffs. Within these sedimentary rocks are dark green andesitic flows and tuffs which form units possibly up to 20 m thick. The sequence in general strikes 10° and dips to the east at 30 to 40° . Graded bedding in siltstones indicates the unit to be the right way up.

In gossanous outcrops the rocks are noticeably more siliceous than is usually found.

Coarser clastic rocks of Unit 2 conformably overlie Unit 1. The commonest rock type within this unit is massive, fine to coarse-grained greywacke (Unit 2a) which is dark grey when fresh but rusty when weathered. Belemnites were found in several outcrops of greywacke. Locally, greywacke can grade into a well-sorted, light brown-grey weathering arkosic sandstone (Unit 2d) with shaly laminations. On the other extreme greywacke can grade rapidly into a coarse volcanic conglomerate (Unit 2b). Clasts are most commonly felsic, subrounded to subangular, and up to 25 cm across. Andesite and sandstone clasts also occur but are less common.

Unit 2c is a distinctive horizon of what is believed to be basaltic tuff. The rock is composed of 1-5 mm, euhedral, dark-green hornblende crystals in a fine-grained, medium-grey matrix. Finer, tuffaceous lenses within the basaltic tuff are contorted, probably due to slumping. The tuff itself is coarsely layered due to size sorting of the hornblende, crystals.

The percentage of siltstone and shale with Unit 2 is difficult to estimate because they weather recessively, whereas the coarser clastic rocks tend to be more resistant and form outcrops. The different geochemical character of the soil over these two units (see Soil Geochemistry section), however, suggests that siltstones and shale are a relatively minor component of unit 2.

Overlying Units 1 and 2, possibly with slight unconformity are andesite flows and breccias belonging to Unit 3. The predominant lithology is a green-grey andesite flow with 1-3 mm feldspar phenocrysts and 1-4 mm pyroxene phenocrysts. Flows generally contain 1% disseminated pyrite. At the north end of the unit grey-green and maroon epidotized volcanic breccia appears.

Unit 3 is believed to be approximately the same age as the underlying sediments based on the similarity between Unit 3 and the andesitic flows which are interbedded with Unit 1.

Units 4 and 5 are predominantly felsic tuffs and flows which are believed to belong to the Upper Cretaceous or Tertiary Ootsa Lake Group. Rhyolite flows (?) are fresh, massive cream-coloured rocks which tend to be well-fractured and barren of sulphides. Felsic tuffs consist of thinly bedded, light grey tuffs which are interbedded over 1-2 m with a creamy, rubbly, firable tuff. These tuffs may occur within massive rhyolite such as Unit 4. Felsic, pyroclastic breccias occur locally but are not widespread. Folding of the tuffs was observed in one outcrop.

Several intrusive units of possible Tertiary age cut the above described units. Flow-banded, limonitic rhyolite (Unit 7) is poorly exposed in a rubbly outcrop along the main Kluskus Road. The rock contains a weak quartz stockwork with minor pyrite and molybdenite mineralization. De-

formation of enclosing sediments outcropping immediately to the north of the rhyolite indicates it was forcibly intruded as a plug.

Dacite (?) of Unit 8a occurs as a 2-3 m wide dyke which can be traced south-southwest for 500m until it runs into a vent breccia. The dacite is grey-green to maroon on fresh surfaces with pale grey feldspar phenocrysts in an aphanitic, locally vesicular matrix. Vesicles are occasionally filled with calcite. Near the breccia the dyke contains 1-2% pyrite as veinlets.

The breccia, where exposed is approximately 50m across and consists of angular, phylllic altered dacitic fragments cemented by calcite. Fragments contain up to 2% pyrite as veinlets and disseminations together with minor disseminated chalcopyrite.

Porphyritic rhyolite (Unit 9) forms two plugs which intrude andesites of Unit 3. Texturally, the rock consists of large salmon-brown K-spar phenocrysts, quartz phenocrysts and biotite books in a pink-brown aphanitic matrix. Disseminated pyrite occurs in trace amounts.

Quartz monzonite porphyry (Unit 10) is the most distinct, continuous unit on the property, forming a 200 to 300 m wide dyke, which can be traced along the east side of the property for three kilometers. On weathered and fresh surfaces the rock has a distinctive pink matrix which contains 2 to 3 mm rounded glassy quartz phenocrysts, and 2 to 3 mm

pink K-spar and white plagioclase phenocrysts. Mafic minerals probably biotite, have been completely chloritized. Quartz monzonite porphyry divides Unit 3 from Units 4 and 5 and has possibly intruded along a fault contact between these units.

Unit 11, located in the southwest corner of the claims consists of flows, tuffs and breccias which are probably part of the Ootsa Lake Group. The most abundant lithology is a dacitic quartz feldspar porphyry with a characteristic deep maroon colour. Maroon tuffs and intermediate breccias are probably related to the dacite flows. Grey vesicular basalt underlies the dacite.

Structure

Units 1 and 2 dip uniformly to the east at 35°, although dips as shallow as 15° and as steep as 60° have been recorded. Folding within these units is restricted in extent and caused by local disturbances such as faulting or intrusions.

Lack of outcrop and marker units makes identification of faulting difficult. A series of northeast-trending faults are believed to offset Unit 10. These faults have not been observed but are based on outcrop distribution, airphoto linears, and strong northeast jointing. These faults cannot be followed with Units 1 and 2.

Northwest-trending linears are believed to mark a fault-contact between Unit 11 and 2.

Mineralization

Economic mineralization observed in outcrops has been identified on Figure by three zones marked A to C.

Zone A:

Zone A consists of limonitic tuffs and sediments mineralized by 2-5% pyrite veinlets and by a stockwork of limonitic, vuggy, white quartz veins. Hoffman (1981) reported tourmaline (?) and fluorite from these veins but their presence could not be confirmed in 1982. Trace amounts of galena and chalcopyrite were noted in some pyrite veinlets.

Mineralization is fracture controlled, which in turn is partly controlled by lithology. Siltstones and shales are intensely fractured andesitic flows within the sediments. A genetic relationship between Unit 7 and mineralization is suggested by the presence of a quartz stockwork in both Unit 7 and zone A, and the proximity and increasing intensity of mineralization toward Unit 7.

Chip sample results for this zone are given below in a north to south sequence.

Zone A Chip Sample Results (ppm)

Sample #	Lithology	Mo	Cu	Pb	Zn	Ag	As	Cd	Sb	Bi	W	Au(ppb)
001-3	Limonitic seds.	8	179	6	80	0.5	2	1	2	3	37	5
001-2	Argillite, silic.tuff	8	147	10	47	0.7	2	1	2	3	96	5
001-1	Qz-veined Siltstone	17	245	10	86	0.7	2	1	2	10	57	395
037	Rhyolite	8	13	7	35	0.1	10	1	2	2	2	5

The sediments are geochemically anomalous in W which suggests the mineralization is part of a weak molybdenum system related to Unit 7. Sample 001-1 averages 0.4 ppm Au over the 3 m samples. This very anomalous Au value suggests that this zone has potential for epithermal precious metal mineralization spatially related to Unit 7.

Zone B:

Zone B is centered on a small hill in the west-central area of RANGE 1. Rocks exposed along road cuts in this area consist of highly fractured, limonitic, thinly bedded felsic tuffs or silicified siltstones. The only mineralization observed in outcrop was 1-2% disseminated pyrite. Analyses for four random chip samples collected over a 4 m radius are reported below.

Zone B Chip Sample Results

Sample #	Mo	Cu	Pb	Zn	Ag	As	Cd	Sb	Bi	W	Au(ppb)
013B-1	2	354	18	4305	1.8	2	72	2	50	2	10
013B-2	2	224	18	457	0.6	2	6	2	4	2	5
013B-3	1	32	8	98	0.2	2	2	2	2	2	5
014	4	81	24	162	0.6	2	2	2	59	2	75

Elevated values for zinc, silver, cadmium, and bismuth in sample 013B-1 probably result from small amounts of sphalerite in the sample. Levinson (1980) reports elevated cadmium levels in peripheral areas of mineral deposits. Sample 014, collected on the south side of the hill is anomalous in gold and bismuth.

Zone C:

Zone C is centred on vent breccia (Unit 8b) related to a dacite dyke (Unit 8a). The breccia is exposed as gossanous rubble along a firebreak bordering a logged area. Observed mineralization consists of pyrite and disseminated chalcopyrite within moderately to intensely phyllitic altered dacitic fragments. Calcite gangue cements the fragments. One chip sample collected across the exposed 35 m width of the breccia is reported below.

Zone C Chip Sample Results

<u>Sample #</u>	<u>Mo</u>	<u>Cu</u>	<u>Pb</u>	<u>Zn</u>	<u>Ag</u>	<u>As</u>	<u>Cd</u>	<u>Sb</u>	<u>Bi</u>	<u>W</u>	<u>Au(ppb)</u>
041 F	1	232	77	210	2.1	124	2	2	12	2	90

Although chalcopyrite was observed in hand specimen, copper is only geochemically anomalous. The breccia is generally anomalous in silver, arsenic, bismuth, and gold, however, exposure is too poor to do any further evaluation at present.

Bulldozer Trenching Program (see Figure 5)

Following the geochemical sampling and preliminary analysis of sample results, a limited program of bulldozer trenching was carried out on the RANGE claims, on L12+00S and L14+00S. A D-8 bulldozer with a 1 metre ripper blade was contracted, and the trenching was carried out during the period September 10 - 15, 1982.

A total of 550 metres of trenching was done in four separate trenches. Once bedrock was reached, the trench bottom was ripped to a depth of 1 metre to assure fresh samples. Overburden thickness varied from 0 to more than 4 metres, with an average of 1.0 metres. No attempt was made to dig deeper than 4 metres to bedrock due to time/cost constraints.

Trench Sampling and Mapping Program (Figure 5, Table 1)

A continuous rock chip sampling program was done in each trench, nominally at 10 metres, closing to 5 metres in areas of sulfide staining occurrence, and presence of brecciated rocks.

Sample results are present in Table 1. In summary, rock geochemistry mimicked the soil results spatially, except that the highest silver values in fresh rock are almost half those encountered in the soils. In each case, the same laboratory, laboratory methods and standards were used. Overburden in the anomalous area is usually 0-.5 metres, so surface leaching of the bedrock may explain the

results. The solitary high gold values of 165 ppb in soils corresponds to 5 ppb in fresh rock. Conversely, the 70 ppb gold at sample site 5031 in Trench 2 corresponds to trace in the corresponding soil samples.

The brecciated zone in Trench 2 contains elevated levels of base metals, silver and gold, from 1+75W to 2+30W, but these values are not duplicated in Trench 3 and 4, which have only two samples at twice background in gold and no elevated silver values. Either the gap between Trench 3 and 4 is the brecciated zone, as evidenced by elevated lead and zinc values.

Sample Collection, Preparation and Analysis

Soil samples were taken at 50 to 100 m intervals on the RANGE soil grid from the top of the B soil horizon, generally a reddish brown iron-rich zone at a depth of 20 to 30 cm. In areas of sulphide mineralization, soil samples were obtained at 25 m intervals.

In all cases, approximately 500 grams of material was saved in a wet strength paper envelope, prenumbered by sampler according to a regular sequence. An orange ribbon was left on site to aid followup which might be undertaken. Sample number and grid location were affixed on aluminum tags to permit long term recovery of sample locations.

Samples were partially dried and shipped by Pacific Western or Greyhound to Vancouver. Acme Analytical then air dried the soil and sediment samples and sieved disaggregated material to minus 80-mesh. Sample splits of 0.5 grams were digested in aqua regia and analyzed by an inductively coupled plasma (ICP) unit for 26 metals (Appendix 1). A listing of analytical results is found in Appendix 2. Field technical information was recorded according to a standard BP Minerals format and is included with the analytical data of Appendix 2.

Method of Data Evaluation

Appendix 2 lists the field technical data and analytical results in three parts, appropriately numbered in the upper right hand corner of each page. Appendix 3 summarizes statistics for data sets grouped according to sample type (see coding format for columns 1 and 2 in Appendix 3). Selection of arithmetic or logarithmic statistics is determined by a coefficient of variation less than 0.5 (arithmetic) or greater than 0.5 (logarithmic) of data sets where the lowest and highest 5% of the values have been ignored (truncated) to prevent outliers adversely influencing the shape of the histogram.

The minimum and maximum values of the truncated survey data and the range of concentrations they represent are indicated, as are the mean, median (value midway in the frequency distribution) and mode (most commonly occurring value). The standard deviation and statistical anomaly threshold (mean plus 2 standard deviation intervals are quoted. Large values of the standard deviation compared to the mean suggest bimodal distributions and anomaly thresholds are best estimated with reference to histograms contained in Appendix 4.

Deviations from normality can be calculated using skewness and kurtosis measurements. A large positive skewness indicates many samples have low values near the mean,

and high values extend far above the mean. A negative skewness represents population with an extended lower tail of values. Kurtosis values for a normal distribution equals

3. Negative kurtosis values (after subtracting 3 from the kurtosis values) result from distributional curves having a flatter top than usual where as positive values represent peaked distributions.

Description of Results

Copper (Figure 4B)

Copper exhibits good regional enhancement for soils on RANGE. The largest copper-rich zone trends north-east from L21+00S, 750W to L11+00S, 25E, with the majority of values in excess of 100 ppm. It is underlain by Hazelton sediments and appears to be both lithologically and structurally controlled. The northern portions of this anomalous region is centered on a vent breccia related to a dacite dyke containing pyrite and disseminated chalcopyrite associated with moderately to intensely altered dacitic fragments.

A smaller anomalous region located at the western extension of L1+00S to L5+00S from the baseline to 550W, lies downslope from zone B. The immediate proximity and similar geochemical expression of the copper-rich soils to the mineralized chip samples suggests additional or broader zones of weakly mineralized quartz veined stockworks.

Copper concentrations obtained from soils underlain by volcanic units are characterized by background copper values except for the odd anomalous sample. Isolated anomalies, especially ones near the southern margins of the survey area on RANGE may-be significant in view of the wide spacing of grid lines and sample density.

Lead (Figure 4C)

The distribution of lead in soils on RANGE exhibits greater variability than that for copper. Lead accumulation

exhibits a relatively high contrast compared to a background of less than 25 ppm. The large copper anomaly, termed the 'dyke zone anomaly' is also lead rich. Dimensions are up to 400 metres wide and extend between L15+00S to L1+00S in a north by northeast manner, and probably structurally and/or lithologically controlled. Maximum values are in the 200 to 250 ppm lead range, 5 to 10 times background.

The other area of enhanced copper in soils, termed the 'northwest zone anomaly', exhibits only slightly increased levels of lead.

Significantly more lead anomalies are located within the volcanic units than was the case for copper. The majority tend to be aligned in an east-west fashion, straddling the most northerly inferred fault.

As was the case for copper, single isolated anomalies, open to the south, merit additional investigation due to the wide sample spacings.

Zinc (Figure 4D)

The zinc distribution is similar to that of copper and lead. Average concentration of zinc in soils range from 80 to 150 ppm. Both the dyke zone and northwest anomaly exhibit significant accumulations of zinc. The northwest zone anomaly, high in copper is also extremely zinc rich, averaging about 700 ppm to a sample high of 1192 ppm. The anomalous region extends from the baseline to the western-most margins of the survey on lines 0+00S to 4+00S.

Enhanced accumulation of zinc up to 4251 ppm zinc also occurs within the dyke zone anomaly. Increased levels of zinc, however, are restricted to close proximity of the dyke.

A third zone of zinc enrichment occurs on L33+00S, from 200E to 800E, and is associated with increased levels of copper and lead. As was the case for copper, no significant anomalies were encountered over the volcanic units on RANGE.

Barium (Figure 4E)

The distribution of barium is markedly different from that of other elements. The northwest zone characterized by anomalous levels of copper and zinc contains background concentrations of barium whereas the dyke zone soils are only moderately enhanced. Significant accumulations of greater than 300 ppm barium are clustered in an east-west trend (L0+00S to 4+00S, from about 700E to 1400E). A five sample anomaly to 818 ppm barium is also outlined along the north-eastern margins of the claim group.

The geological environment and underlying rhyolitic flows associated with these unusually high barium contents, increasing and open to the northeast, merit additional follow-up and raises the distinct possibility of a massive sulphide Kuroko type deposit to the east.

One other significant anomalous barium zone is outlined on RANGE, along L33+00S from 200W to 700W. Maximum values range up to 948 ppm barium and are associated with anomalous lead and zinc values.

Gold (Figure 4F)

Gold contents are typically of the detection limit of 5 ppb on RANGE. Distribution of gold rich soils tends to be extremely spotty exhibiting no aerial continuity. A high gold value of 165 ppb is associated with the central portions of the dyke zone.

Silver (Figure 4G)

Silver contents are typically very low on RANGE. Anomaly threshold is estimated at 1.0 ppm. Six isolated and one aerally continuous anomalies are defined on this basis. Maximum values in all cases are in the range of 2 to 5 ppm.

The dyke zone anomaly exhibits significant silver enrichment in the 1.8 to 33 range compared to a background of less than 0.4 ppm. The anomalous region is up to 500 metres across and 500 metres in length centered on a dacitic dyke and its related breccia. By contrast, the northwest zone is characterized by background levels of silver.

The isolated anomalies might be significant in view of the wide spacing of grid lines and sampling density, especially the ones located at the southern margins of the sampling grid, which also exhibit enhanced copper, lead and zinc contents.

Arsenic (Figure 4H)

The distribution of arsenic is similar to that of copper, zinc, and iron. Most of the soils are characterized by concentrations of less than 25 ppm arsenic. Broad regional clustering of arsenic rich soils restricted to the northwest portion of the survey area, suggests a possible lithological or structural control. By contrast, soils associated with the volcanic units located to the east contain background levels of less than 15 ppm arsenic.

The broad north by northwest trend that characterizes the dyke zone anomaly also contains enhanced accumulations of arsenic. Significant concentrations of up to 350 ppm centered over the dyke and its related breccia coincides with increased concentrations of copper, lead, zinc, and silver. Increased levels up to 413 ppm arsenic were also obtained, from the northwest zone, although distribution of arsenic-rich soils is more localized.

Molybdenum (Figure 4I)

Molybdenum levels are generally at the detection limit of 1 ppm on RANGE. By contrast a cluster of strongly

enhanced values of 11 to 34 ppm is associated with the copper and zinc rich northwest anomaly, possibly reflecting a weak porphyry system.

Iron (Figure 4K)

Iron variability extends over a significant range of values. Most soils are average, containing less than 3.2% iron. Iron accumulation from 4% to 7% levels and up to 10% is particularly prominent within both basemetal rich, barite poor dyke zone and northwest zone. The iron-rich zone is highly analogous to the that of zinc. Presence of pyrite in chip samples obtained from both anomalous zones, suggesting high pyrite content within the Hazelton sediments is contributing to the anomalous iron distribution. The volcanic units on RANGE by contrast are not enriched in iron contents.

Manganese (Figure 4K)

Manganese variability extends over a significant range of values. Average concentrations of less than 300 ppm manganese characterizes the majority of sample. The distribution of manganese-rich samples (up to 3500 ppm) corresponds generally to that of iron, although a greater number are found within the volcanic units. Anomalous concentrations of manganese are associated with both major base metal anomalies, aerally not as widespread.

Nickel (Figure 4H)

The distribution of nickel is probably lithologically and/or structurally controlled on RANGE. A broad regional anomaly averaging about 25 ppm nickel up to 159 ppm trends north by northeast parallels the dyke zone anomaly. Highest concentrations of nickel being in close proximity to the dacitic dyke and its related breccia. The northwest zone anomaly exhibits a cluster of significantly high accumulations of up to 88 ppm nickel. Felsic volcanics east of these two anomalous zones are characterized by soils with nickel contents less than 9 ppm.

Vanadium (Figure 4K)

The distribution of vanadium is probably geologically controlled. A broad regional anomaly trends north-northwest and corresponds in aerial extent to the dyke zone anomaly. Concentrations greater than 80 ppm vanadium are centered over the dacitic dyke. The northwest zone is also enriched in vanadium. Soils overlying volcanic units on RANGE have significantly lower concentrations.

Aluminum (Figure 4K)

The aluminum content of soils reflect geologic and sampling parameters. Position of aluminum-rich zones correspond to that of vanadium. The two important base metal anomalies contain enhanced concentrations of aluminum up to 2.5%.

Magnesium (Figure 4K)

Magnesium exhibits a narrow range of concentrations. Maximum values range around 1.1% magnesium, with the majority of samples averaging less than 0.5%. Magnesium distribution is similar to that of aluminum.

Potassium (Figure 4K)

Potassium in soils on RANGE exhibits very little range in concentration and as consequence, its distribution is highly variable. High values cluster in the same general location as high values of aluminum and barium, but base metal-rich-areas are reflected by average potassium contents.

Calcium (Figure 4K)

The distribution of calcium basically follows that of barium. Both the dyke zone and northwest anomalies exhibit moderate to strong enhancement of calcium.

Strontium (Figure 4K)

Strontium follows calcium in distribution.

Chromium (Figure 4K)

Chromium in soils on RANGE exhibits a very narrow concentration, with most samples averaging less than 16 ppm. Despite the low variability, a broad regional clustering of values parallels the dyke zone anomaly characterized by chromium contents up to 35 ppm.

This north by northwest trend probably reflects lithological or structural controls.

Discussion of Results

Three anomalous zones are identified in soil on RANGE. All three anomalies are reflected primarily by their copper, lead, zinc, and silver contents which for most cases exceeds anomaly threshold of 50 ppm, 40 ppm, 500 ppm and 0.8 ppm respectively.

The largest of the three labelled "dyke zones" by virtue of an apparent association with a dacitic dyke, exhibits anomalous extensions both to the northeast and southwest of known dyke and breccia related material, probably reflecting structural controls. This zone also contains anomalous concentrations of iron, manganese, chromium, and arsenic.

The second largest anomalous zone labelled "northwest" has a distinctively different anomalous geochemical signature than that of the other two. This zone is characterized by molybdenum, copper, and zinc-rich soils, with little to no precious metal content. Rock chip geochemistry and detailed mapping relate the anomalous concentrations to a broad weakly mineralized quartz stockwork, reflecting a minor porphyry system.

A third anomalous zone is located at the southern extremities of the survey area. Despite the wide sample spacing, significant accumulations of copper, lead, zinc and spot silver highs were obtained.

The objective of exploration on RANGE was to discover a mineral occurrence similar to the Granges Capoose prospect on Fawnie Nose. Geochemical study of what was to become the three main Granges prospects was conducted in 1971 (Hoffman, 1976) and the following association could be defined.

1. No. 3 zone of Granges, a predominantly sphalerite bearing zone in volcanioclastic sediments. The No. 3 zone was discovered in 1976 on followup of the stream sediment anomaly reported by Hoffman (1976). Associated elements: weak, copper, lead, zinc, manganese, silver, weak gold, arsenic, cobalt.
2. No. 1 zone of Granges, predominantly silver bearing zone associated with a white, altered rhyolite. No. 1 is the highest grade silver zone. Associated elements: copper, weak lead, zinc, strong manganese, silver, gold, arsenic, cobalt, mercury.
3. No. zone of Granges, a predominantly silver bearing zone with some associated gold credits. Geology comprises volcanic units intruded by a white rhyolite dike and represents the largest of the potential ore zones. Associated elements: copper, lead, weak zinc, silver, gold, arsenic, mercury.

Table 1 summarizes relationships with respect to metal associations at each of the three main anomalies on RANGE and similarities with the dyke and southern zones can be seen with the metal distributions of the Granges deposit.

Anomalous zones associated with base-metal silver highs require more detailed geological mapping and sampling to test their geological affiliation.

TABLE 1

Metal Associations of the Three Main Anomalous Zones on RANGE

	<u>Dyke Zone</u>	<u>Northwest Zone</u>	<u>Southern Zone</u>
Copper	XX	XX	X
Lead	XX	X	XX
Zinc	XX	XX	XX
Iron	XX	X	X
Manganese	XX	X	X
Silver	XX	-	X
Gold	X	-	-
Arsenic	XX	XX	-
Molybdenum	-	XX	-
Barium	-	-	-
Chromium	XX	-	-

X - Moderately high values

XX - Very high values

Conclusions

Three anomalous zones are identified on RANGE. The most outstanding is over 1 km long and rich in copper, lead, zinc, silver, arsenic, iron and chromium. Central portions of the zone has been trenched, and enhanced multi-metal concentrations have been attributed to a dacitic dyke and related breccia material. Significant multi-metal accumulations trending northeast and southwest from the dyke, merit further geological investigation, by mapping and trenching.

Trenching and more detailed mapping is also suggested for the northwest zone anomaly which exhibits high molybdenum, copper and zinc contents.

The southern zone is reflected by appreciable copper, lead, zinc, silver and barium contents, and is open to the south. More detailed soil sampling and geological mapping at 1:5,000 scale is suggested to test its potential.

Subject: Analytical procedure used to determine Aqua Regia soluble gold
in geochemical samples.
Re: 1982 Project 505 Gold analyses.

1. Method of Sample Preparation

- (a) Geochemical soil, silt or rock samples were received in the laboratory in wet-strength 4 x 6 Kraft paper bags or rock samples sometimes in 8" x 12" plastic bags.
- (b) The dried soil and silt samples were sifted by hands using a 8" diameter 80-mesh stainless steel sieve. The plus 80-mesh fraction was rejected and the minus 80-mesh fraction was transferred into a new bag for analysis later.
- (c) The dried rock samples were crushed by using a jaw crusher and pulverized to 100 - mesh or finer by using a disc mill. The pulverized samples were then put in a new bag for later analysis.

2. Method of Digestion

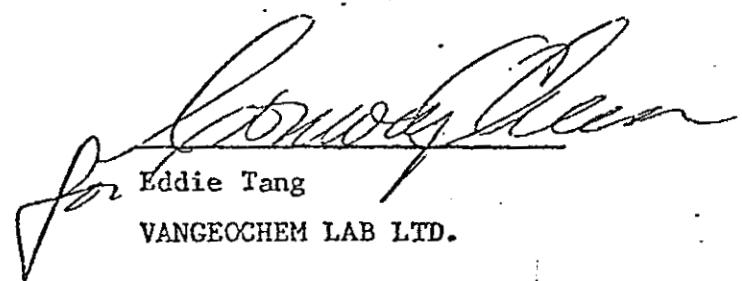

- (a) 5.00 - 10.00 grams of the minus 80-mesh samples were used. Samples were weighed out by using a top-loading balance into beakers.
- (b) 20 ml of Aqua Regia (3:1 HCL : HNO₃) were used to digest the samples over a hot plate vigorously.
- (c) The digested samples were filtered and the washed pulps were discarded and the filtrate was reduced to about 5 ml.
- (d) The Au complex ions were extracted into diisobutyl ketone and thiourea medium. (Anion exchange liquids "Aliquot 336").

(e) Separate Funnels were used to separate the organic layer.

3. Method of Detection

The gold analyses were detected by using a Techtron model AA5 Atomic Absorption Spectrophotometer with a gold hollow cathode Lamp. The results were read out on a strip chart recorder. A hydrogen lamp was used to correct any background interferences. The gold values in parts per billion were calculated by comparing them with a set of gold standards.

4. The analyses were supervised or determined by Mr. Conway Chun or Mr. Eddie Tang and his laboratory staff.

Re: 1982 Project 505 I C P Analyses.

1. Method of Sample Preparation

- (a) Geochemical soil, silt, lake sediments or rock samples were received in the laboratory in wet-strength $3\frac{1}{2}$ x $6\frac{1}{2}$ Kraft paper bags and rock samples in 4" x 6" Kraft paper bags.
- (b) The wet samples were dried in a ventilated oven.
- (c) The dried soil and silt samples were sifted by hands using a 8" diameter 80-mesh stainless steel sieves. The plus 80-mesh fraction was rejected and the minus 80-mesh fraction was transferred into a new bag for analysis later.
- (d) The dried rock samples were crushed by using a jaw crusher and pulverized to 100-mesh or finer by using a disc mill. The pulverized samples were then put in a new bag for later analysis.

2. Method of Digestion

- (a) 0.500 gram of -80 mesh sample was used.
- (b) Samples were digested in a hot water bath with conc. HNO_3 and conc. HCl acids.
- (c) The digested samples were diluted to a fixed volume and shaken well.

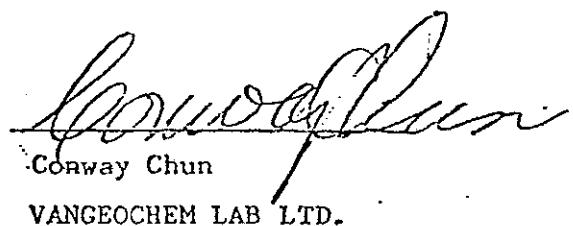

... 2

3. Method of Analysis

The ICP analyses elements were determined by using Jarrel Ash, model 885. Direct reading emission spectraph of a inductive coupled plasma excitation source. All major matrix and trace elements are interelement corrected to trace elements. All data is entered into Apple II plus, stored on floppy discs, and printed by Epson 100.

4. Analysts

The analyses were supervised by Mr. Dean Toye of Acme Lab Ltd. and his staff.

Conway Chun

APPENDIX 5
Statement of Costs

STATEMENT OF COSTSRANGE CLAIMS - GROUP A
Geological, Geochemical, and Trenching Program1. BP LABOUR (Field and office-June 10 - October 19, 1983)

Project Geologist - Michael Smith	
24 days @ \$200/day	\$4,800.00
Geochemist - Stan Hoffman	
8 days @ \$275/day	2,200.00
Geologist - Doug Chen	
6 days @ \$116/day	696.00
Geological Assistant - Ian Fyfe	
21 days @ \$76/day	1,596.00
Geological Assistant - Dan Hicks	
35 days @ \$64/day	2,240.00
Geological Assistant - Andrew Smith	
16 days @ \$73/day	1,168.00
Linecutter - Warren Cummings	
4 days @ \$81/day	<u>324.00</u>
	\$13,024.00

2. CONTRACT LABOUR

i) Linecutting - R.T. Explorations	\$ 2,775.00
ii) Geological Services - Bob Cann, SMDC	
23 days @ \$212/day	\$ 4,876.00
iii) Bulldozer Rental - includes mobilization/ demobilization	<u>\$ 4,183.00</u>

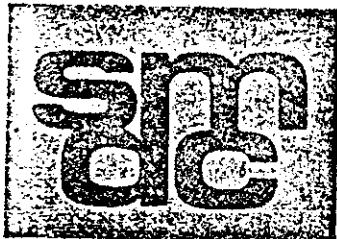

<u>Subtotal</u>	\$24,858.00
-----------------	-------------

NOTE: When the statement of costs was filed on October 15, 1982, an estimate was made of a total expenditure of \$65,000, of which \$10,000 was for the trenching and \$55,000 for geotechnical surveys. Therefore, the money to be credited to the PAC account should be amended to \$31,472.

	<u>Subtotal</u>	\$24,858.00
3. <u>RENTAL VEHICLES</u>		
Four wheel drive vehicle - rental pro-rated for project use, gas, oil, spares, and end of season repair costs		\$ 3,589.39
4. <u>TRAVEL EXPENSES</u>		
Airfares, Vancouver - Prince George		1,014.30
5. <u>FIELD SUPPLIES</u>		1,057.39
6. <u>FIELD ACCOMMODATION</u>		
Kluskus Forestry Camp (BP and contractor crews) \$36.30/man day X 135 man days		3,850.81
7. <u>GEOCHEMICAL ANALYSIS</u>		
800 samples (rock and soil) by ICP and AA gold		8,409.15
8. <u>DATA PROCESSING</u>		
Geochemical Results		2,091.15
9. <u>PHOTOMOSAIC</u>		1,500.00
10. <u>LICENCES AND FILING FEES</u>		994.00
11. <u>OFFICE SUPPLIES AND REPRODUCTION</u>		116.08
12. <u>DRAFTING SERVICES</u>		105.94
13. <u>TELECOMMUNICATIONS</u>		224.94
14. <u>FREIGHT CHARGES</u>		161.50

APPENDIX 6
List of Qualifications

STATEMENT OF QUALIFICATIONS - Michael D. Smith

I, Michael Smith of Suite 700 - 890 West Pender Street in Vancouver in the Province of British Columbia,
Do Hereby State:

1. That I am a graduate of Brock University, St. Catherine, Ontario, where I obtained a B.Sc. (Hons.) degree in Geology in 1975.
2. That I am a Fellow of the Geological Association of Canada.
3. That I have been active in mineral exploration since 1961.
4. That I have practised my profession continuously as a geologist since 1975.

Vancouver, B.C.

Michael D. Smith
Geologist
BP Minerals Limited

List of Qualifications - P.F. Matysek

BSc 1980 - University of Toronto (Hons. Geology)

MSc 1981-1983 - University of British Columbia
(Geochemistry) (to be completed in 1983)

List of Publications

1. Matysek, P.F., 1980

A Preliminary Evaluation of Categorized Field Observations for Regional Stream Sediment Samples.
B.C. Ministry of Energy, Mines and Petroleum Resources, Geological Fieldwork, 1980, Paper 1981-1, pp 148-158.

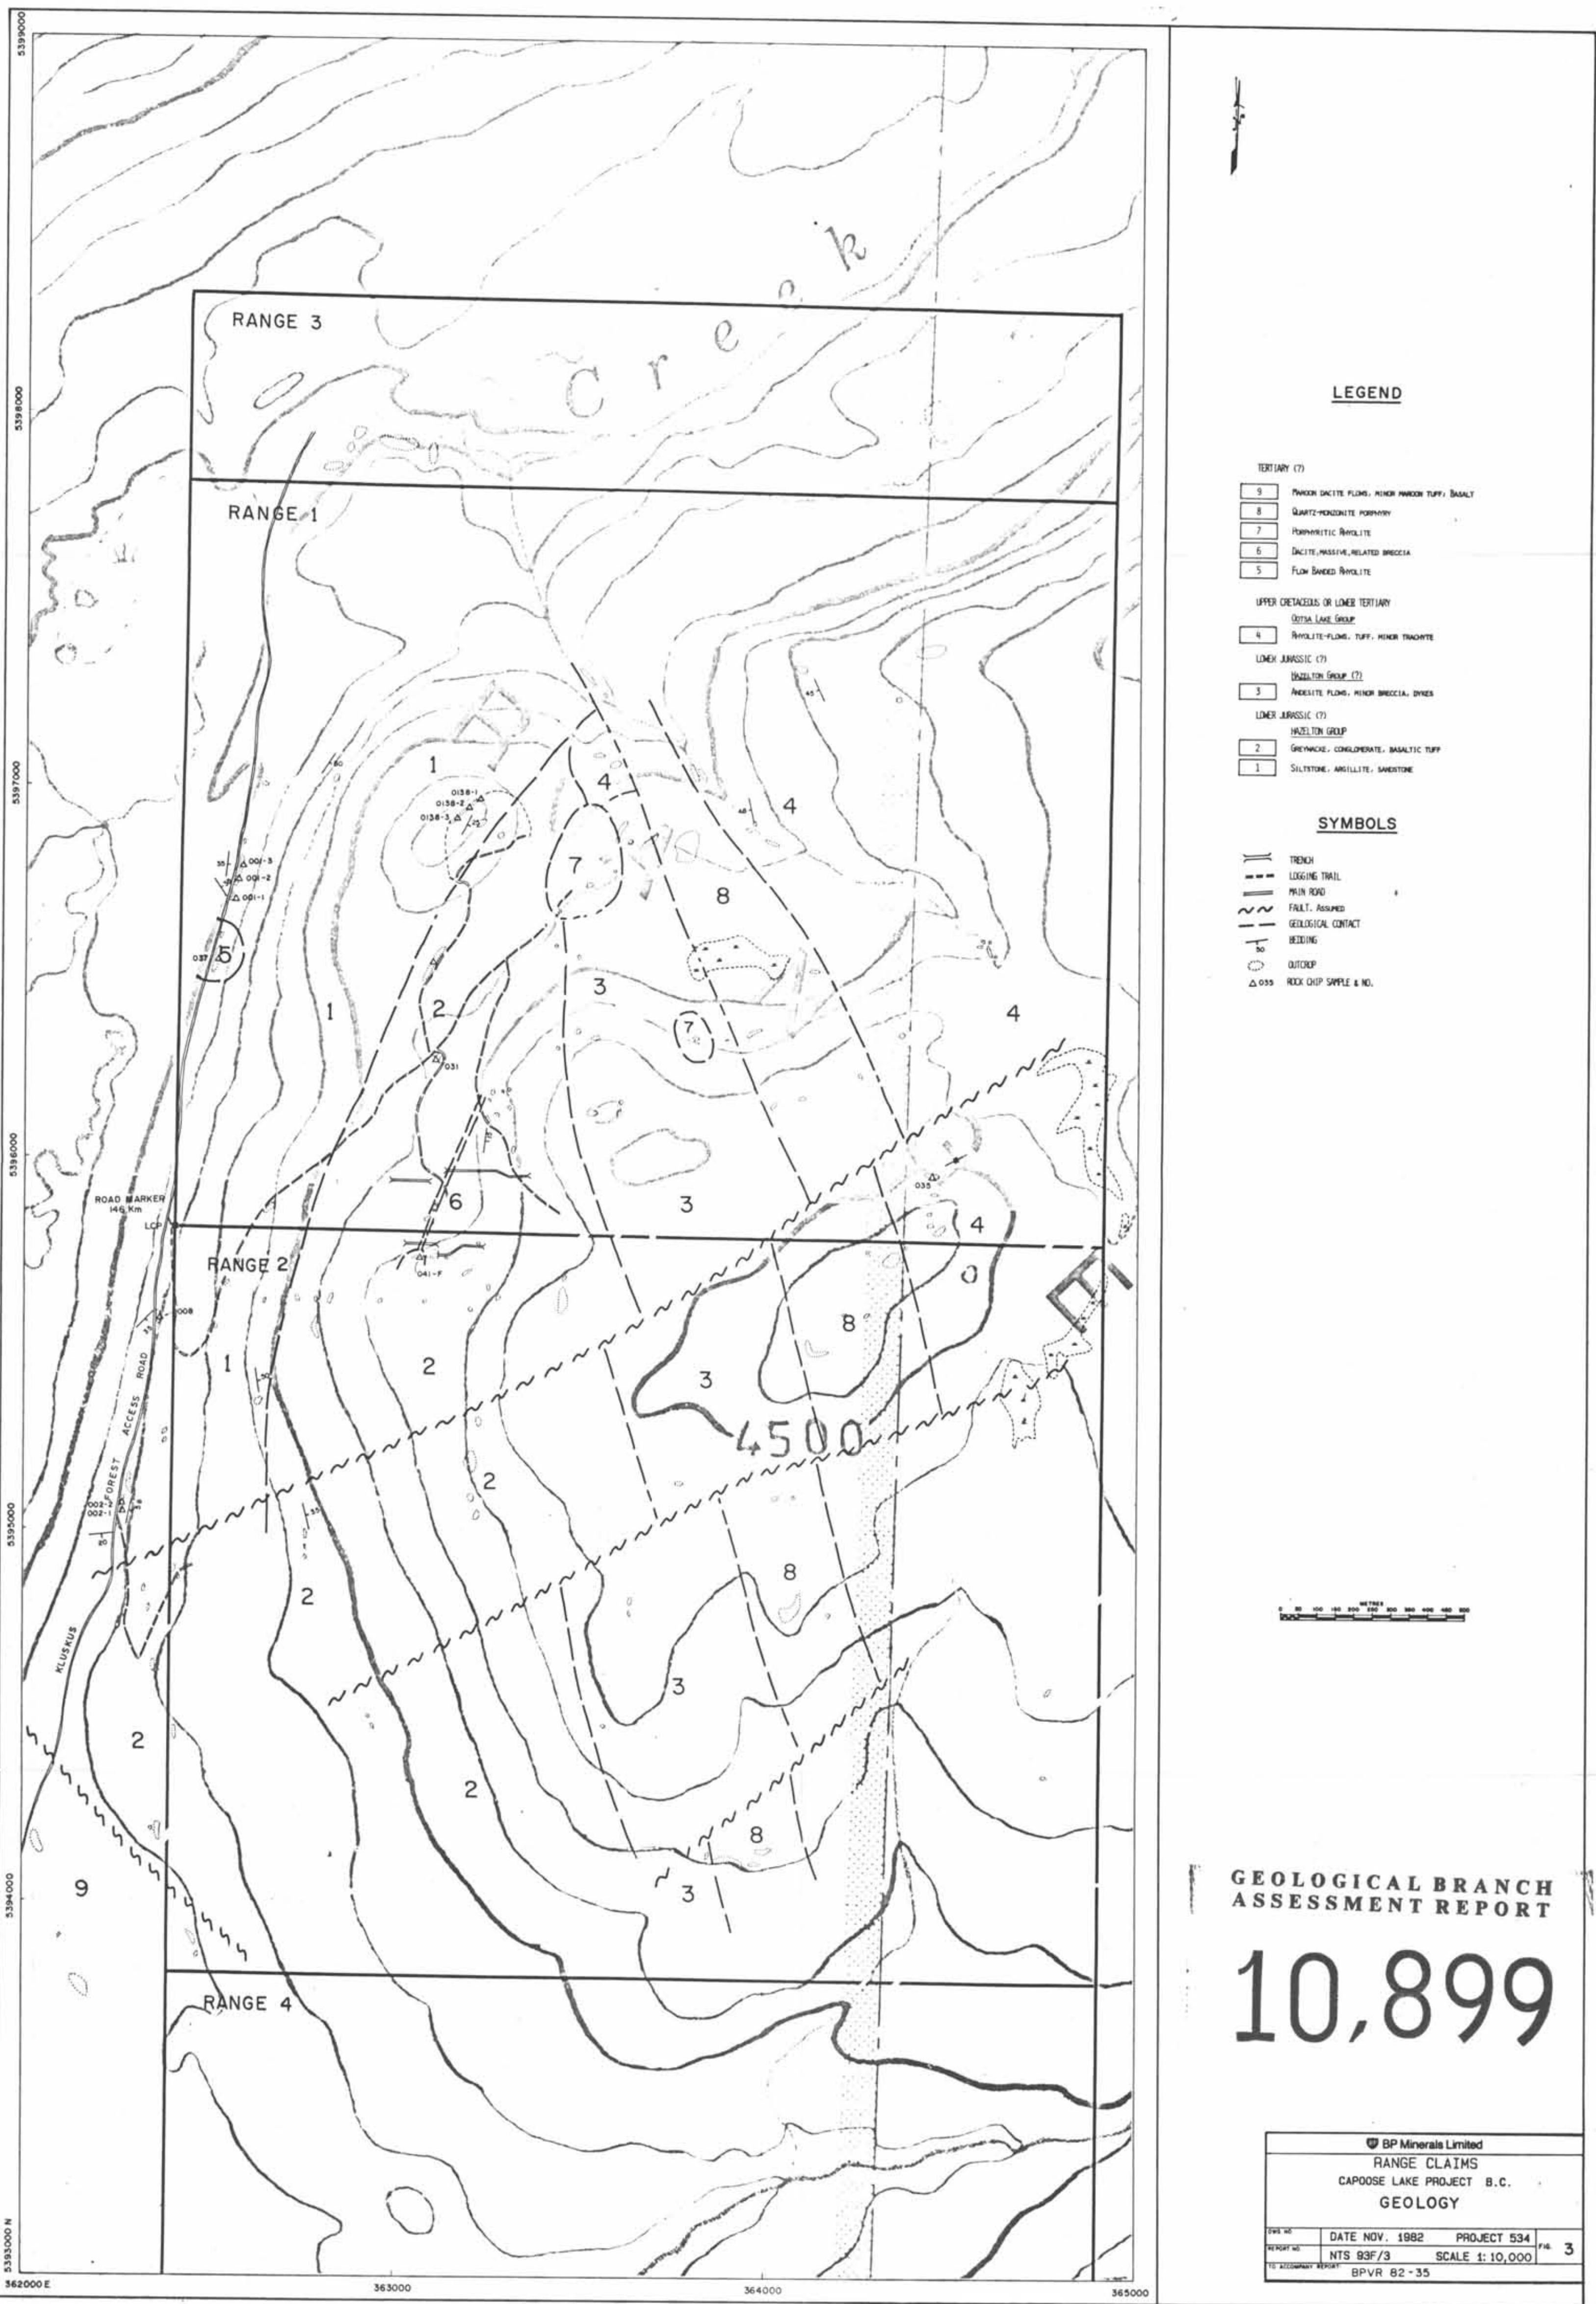

2. Matysek, P.F. et al, 1981

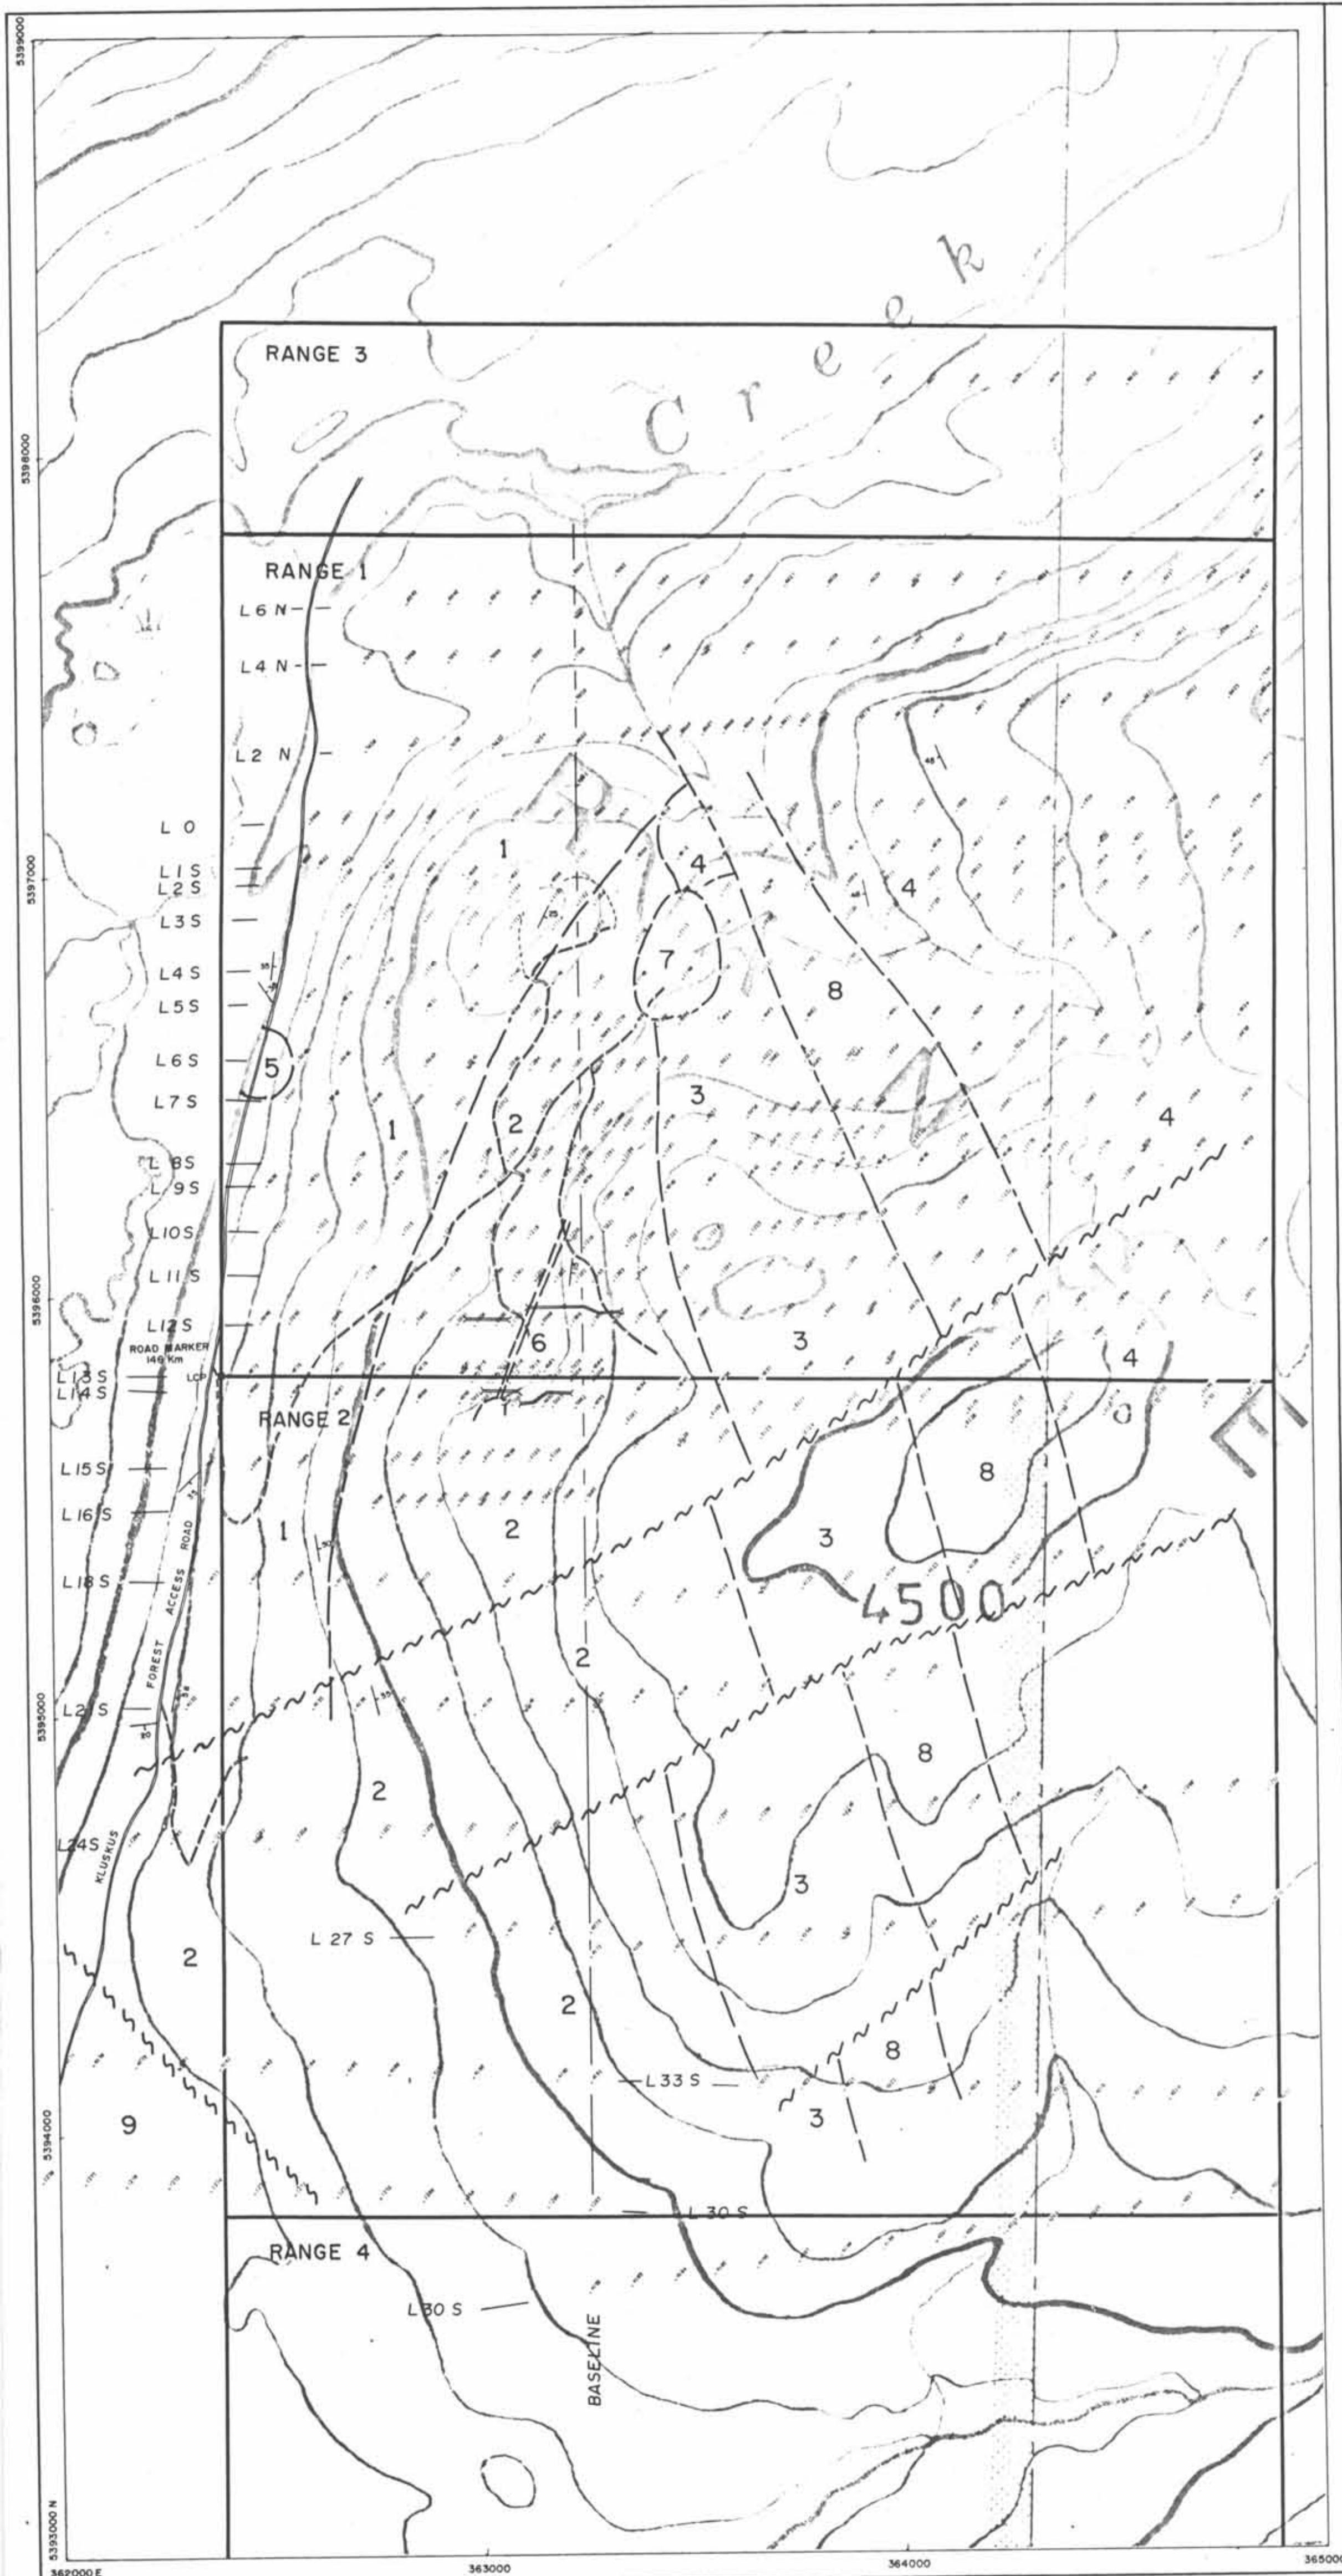

A Rapid Anomaly Recognition and Ranking for Multielement Regional Stream Sediment Surveys.
B.C. Ministry of Energy, Mines and Petroleum Resources, Geological Fieldwork, 1981, Paper 1982-1, pp 176-186.

List of Memberships

1. Canadian Institute of Mining and Metallurgy, since 1980.

2. Association of Exploration Geochemists, since 1980.
