CERTIFICATE

I, the undersigned, of the City of Calgary in the Province of Alberta,
do hereby certify that:

1. I am a consulting Geologist with the firm of Taiga Consultants Ltd.
with offices at #100, 1300 - 8th St. S.W., Calgary, Alberta.
2. I am a graduate of the University of Calgary (B.Sc. Geology, 1976).
3. I have practised my profession for seven years since graduation.
4. I am a member in good standing since 1979 of the Association of
Professional Engineers, Geologists and Geophysicists of Alberta.
5. I have personally worked on the Waneta 1 - 10 mineral claims, and
supervised exploration work carried out thereon.

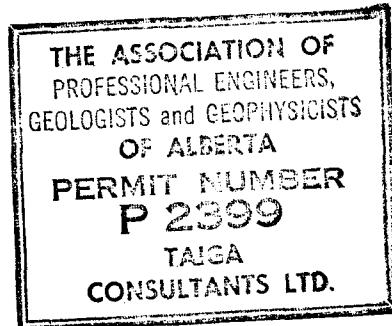

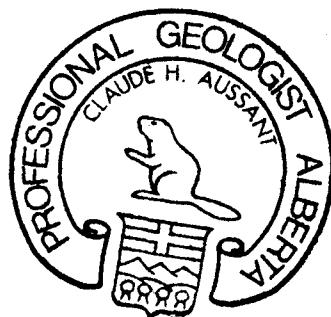

Respectfully submitted,

Claude H. Aussant

October 1983

Claude H. Aussant, B.Sc., P.Geol.

INTRODUCTION

During the period July 22 to August 4, 1983, a total of 30 man days of exploration work were carried out at the Waneta 1 - 10 mineral claims, located along Pend D'Oreille River in southeastern British Columbia. This work consisted of reconnaissance geological mapping, prospecting, stream sediment and rock sampling, grid-controlled soil geochemical sampling, and ground VLF-EM surveying.

This exploration approach was intended to confirm the underlying geology of the property, to identify areas containing potential replacement and disseminated gold mineralization, and to examine in greater detail any such potentially mineralized areas.

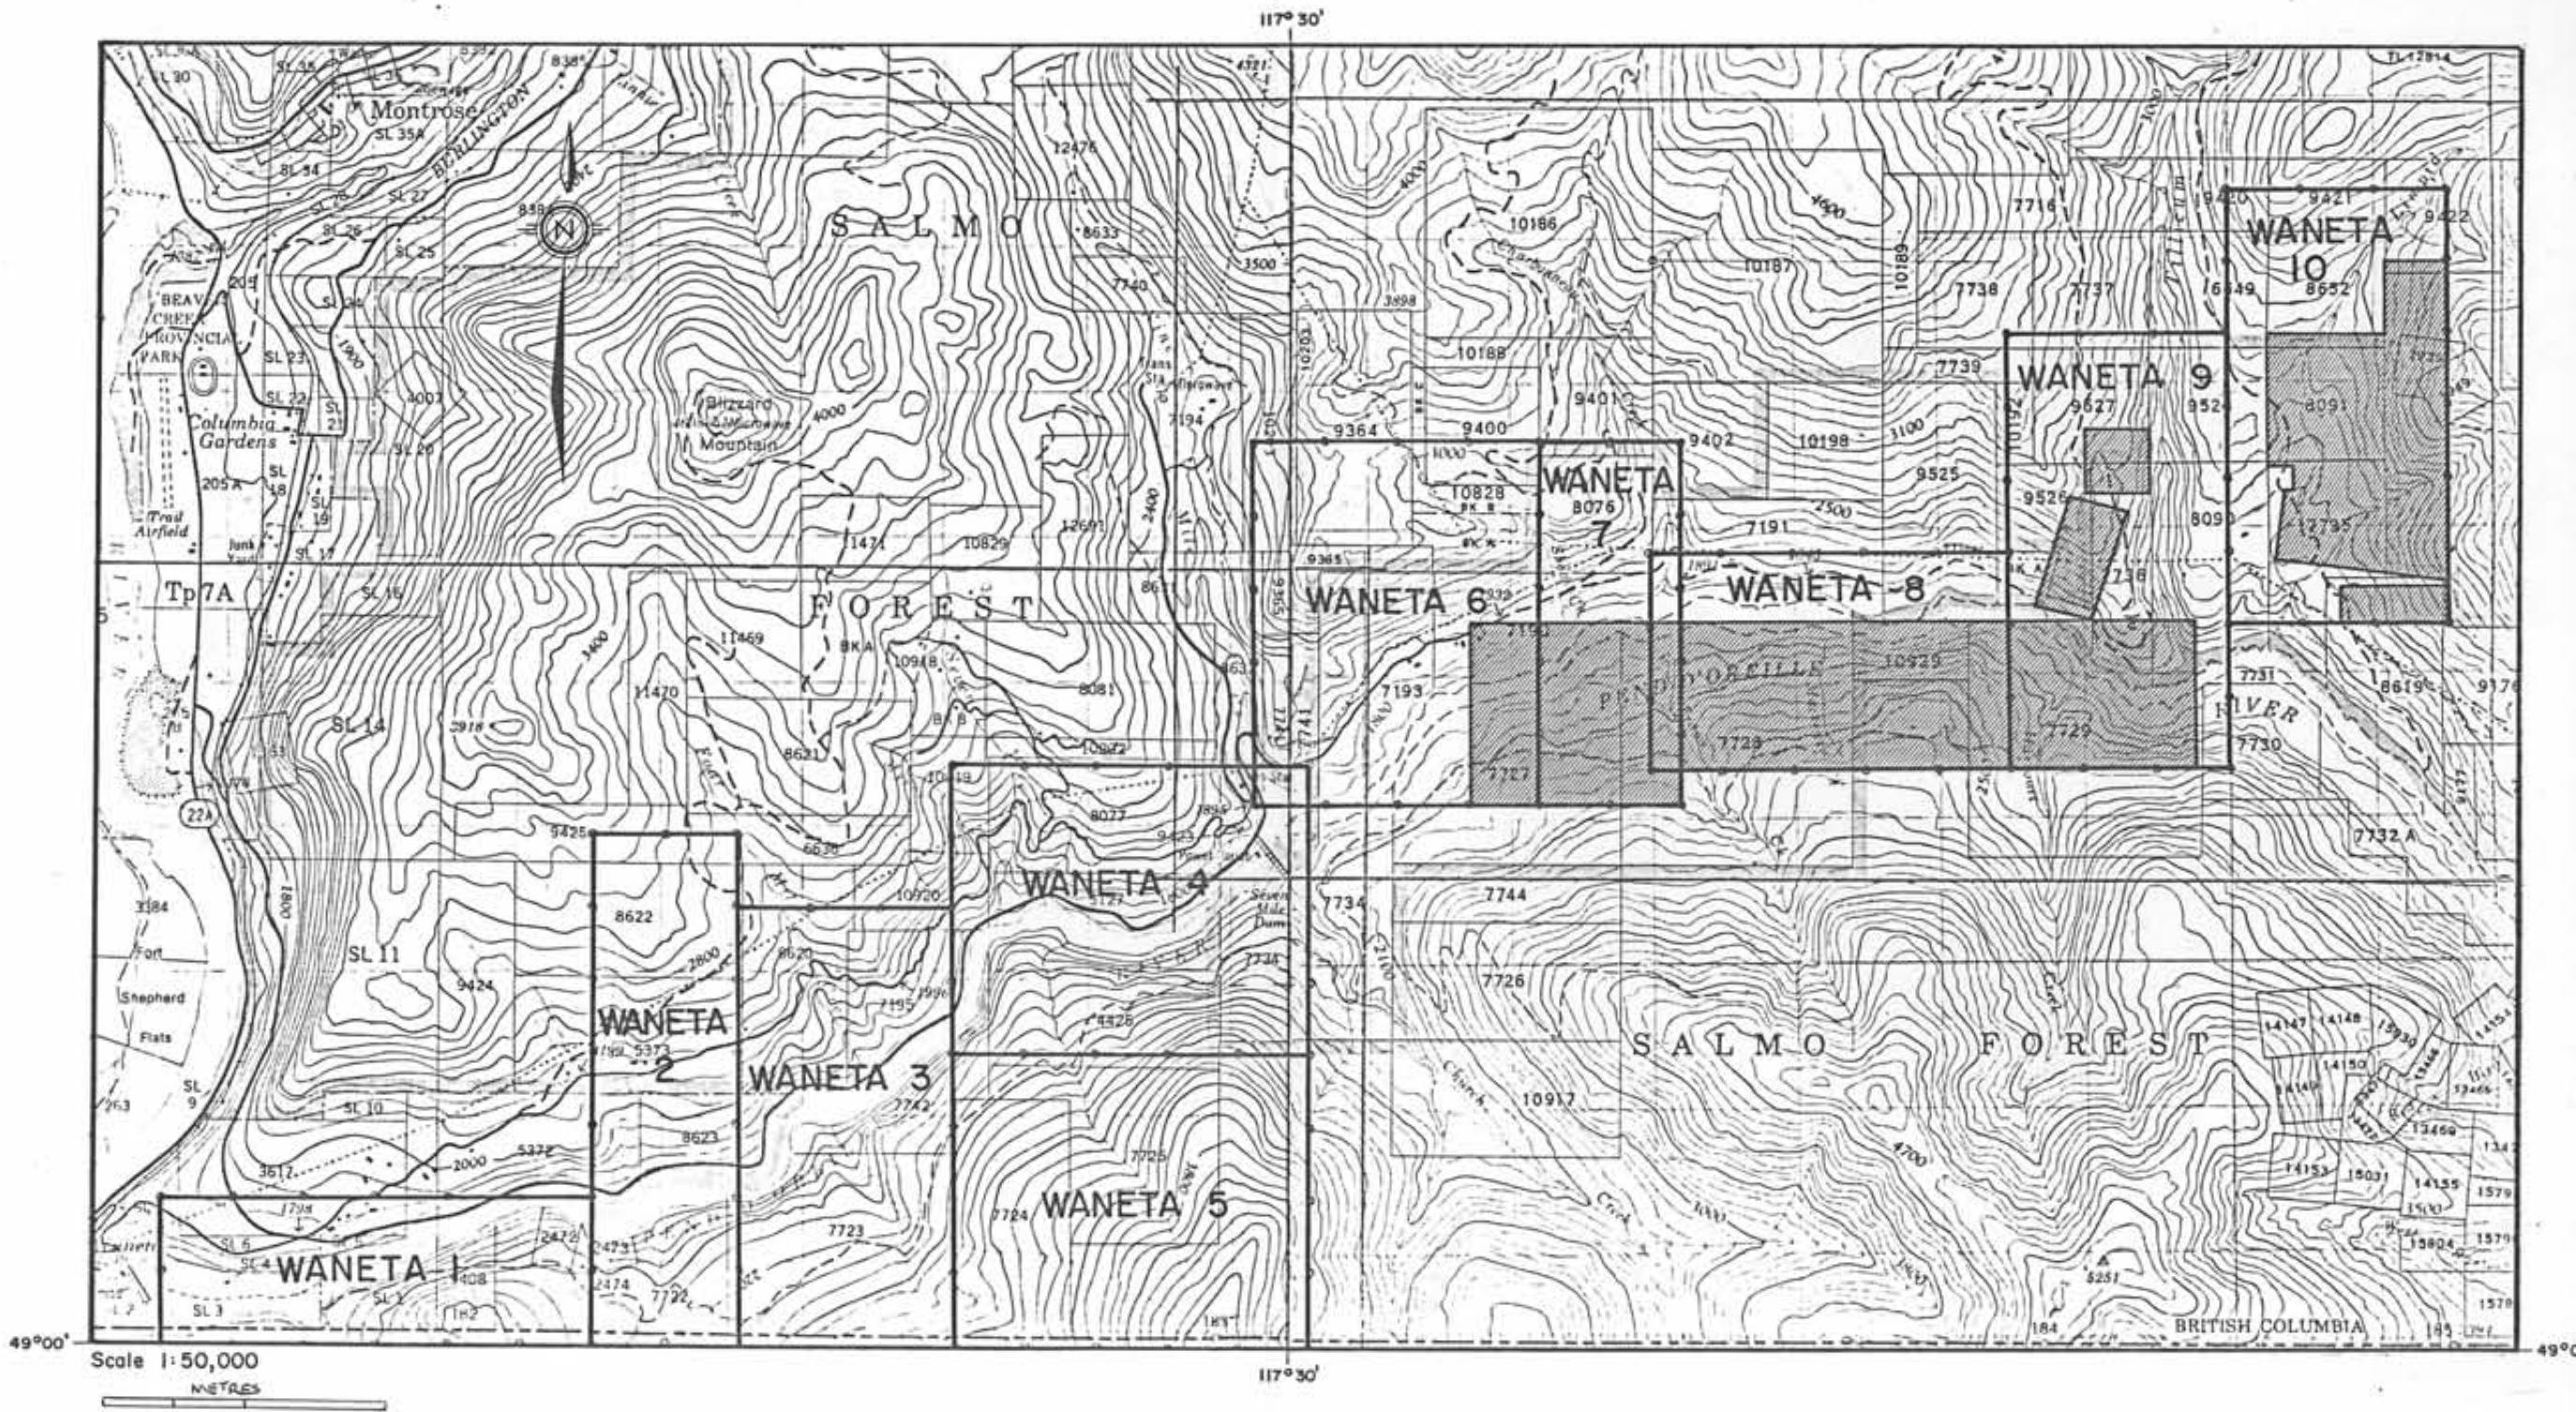

Location and Access

The location and access to the property are illustrated on Figure 1. The claim group is situated in southern British Columbia along Pend D'Oreille River, 12 km southeast of Trail, B.C. The property extends from the Waneta Dam and the international boundary, east and north along Pend D'Oreille River to Limpid Creek.

The property is accessible by B.C. Highway 22A (south from Montrose) and the Seven-Mile Dam all-weather road which crosses the Waneta 1 - 4 claims. The Seven-Mile Dam road is extended by a gravel logging road which leads to Nelway, and traverses the Waneta 6 - 9 claims. Numerous secondary roads, old logging roads, and powerline trails traverse the remainder of the property.

Property and Ownership

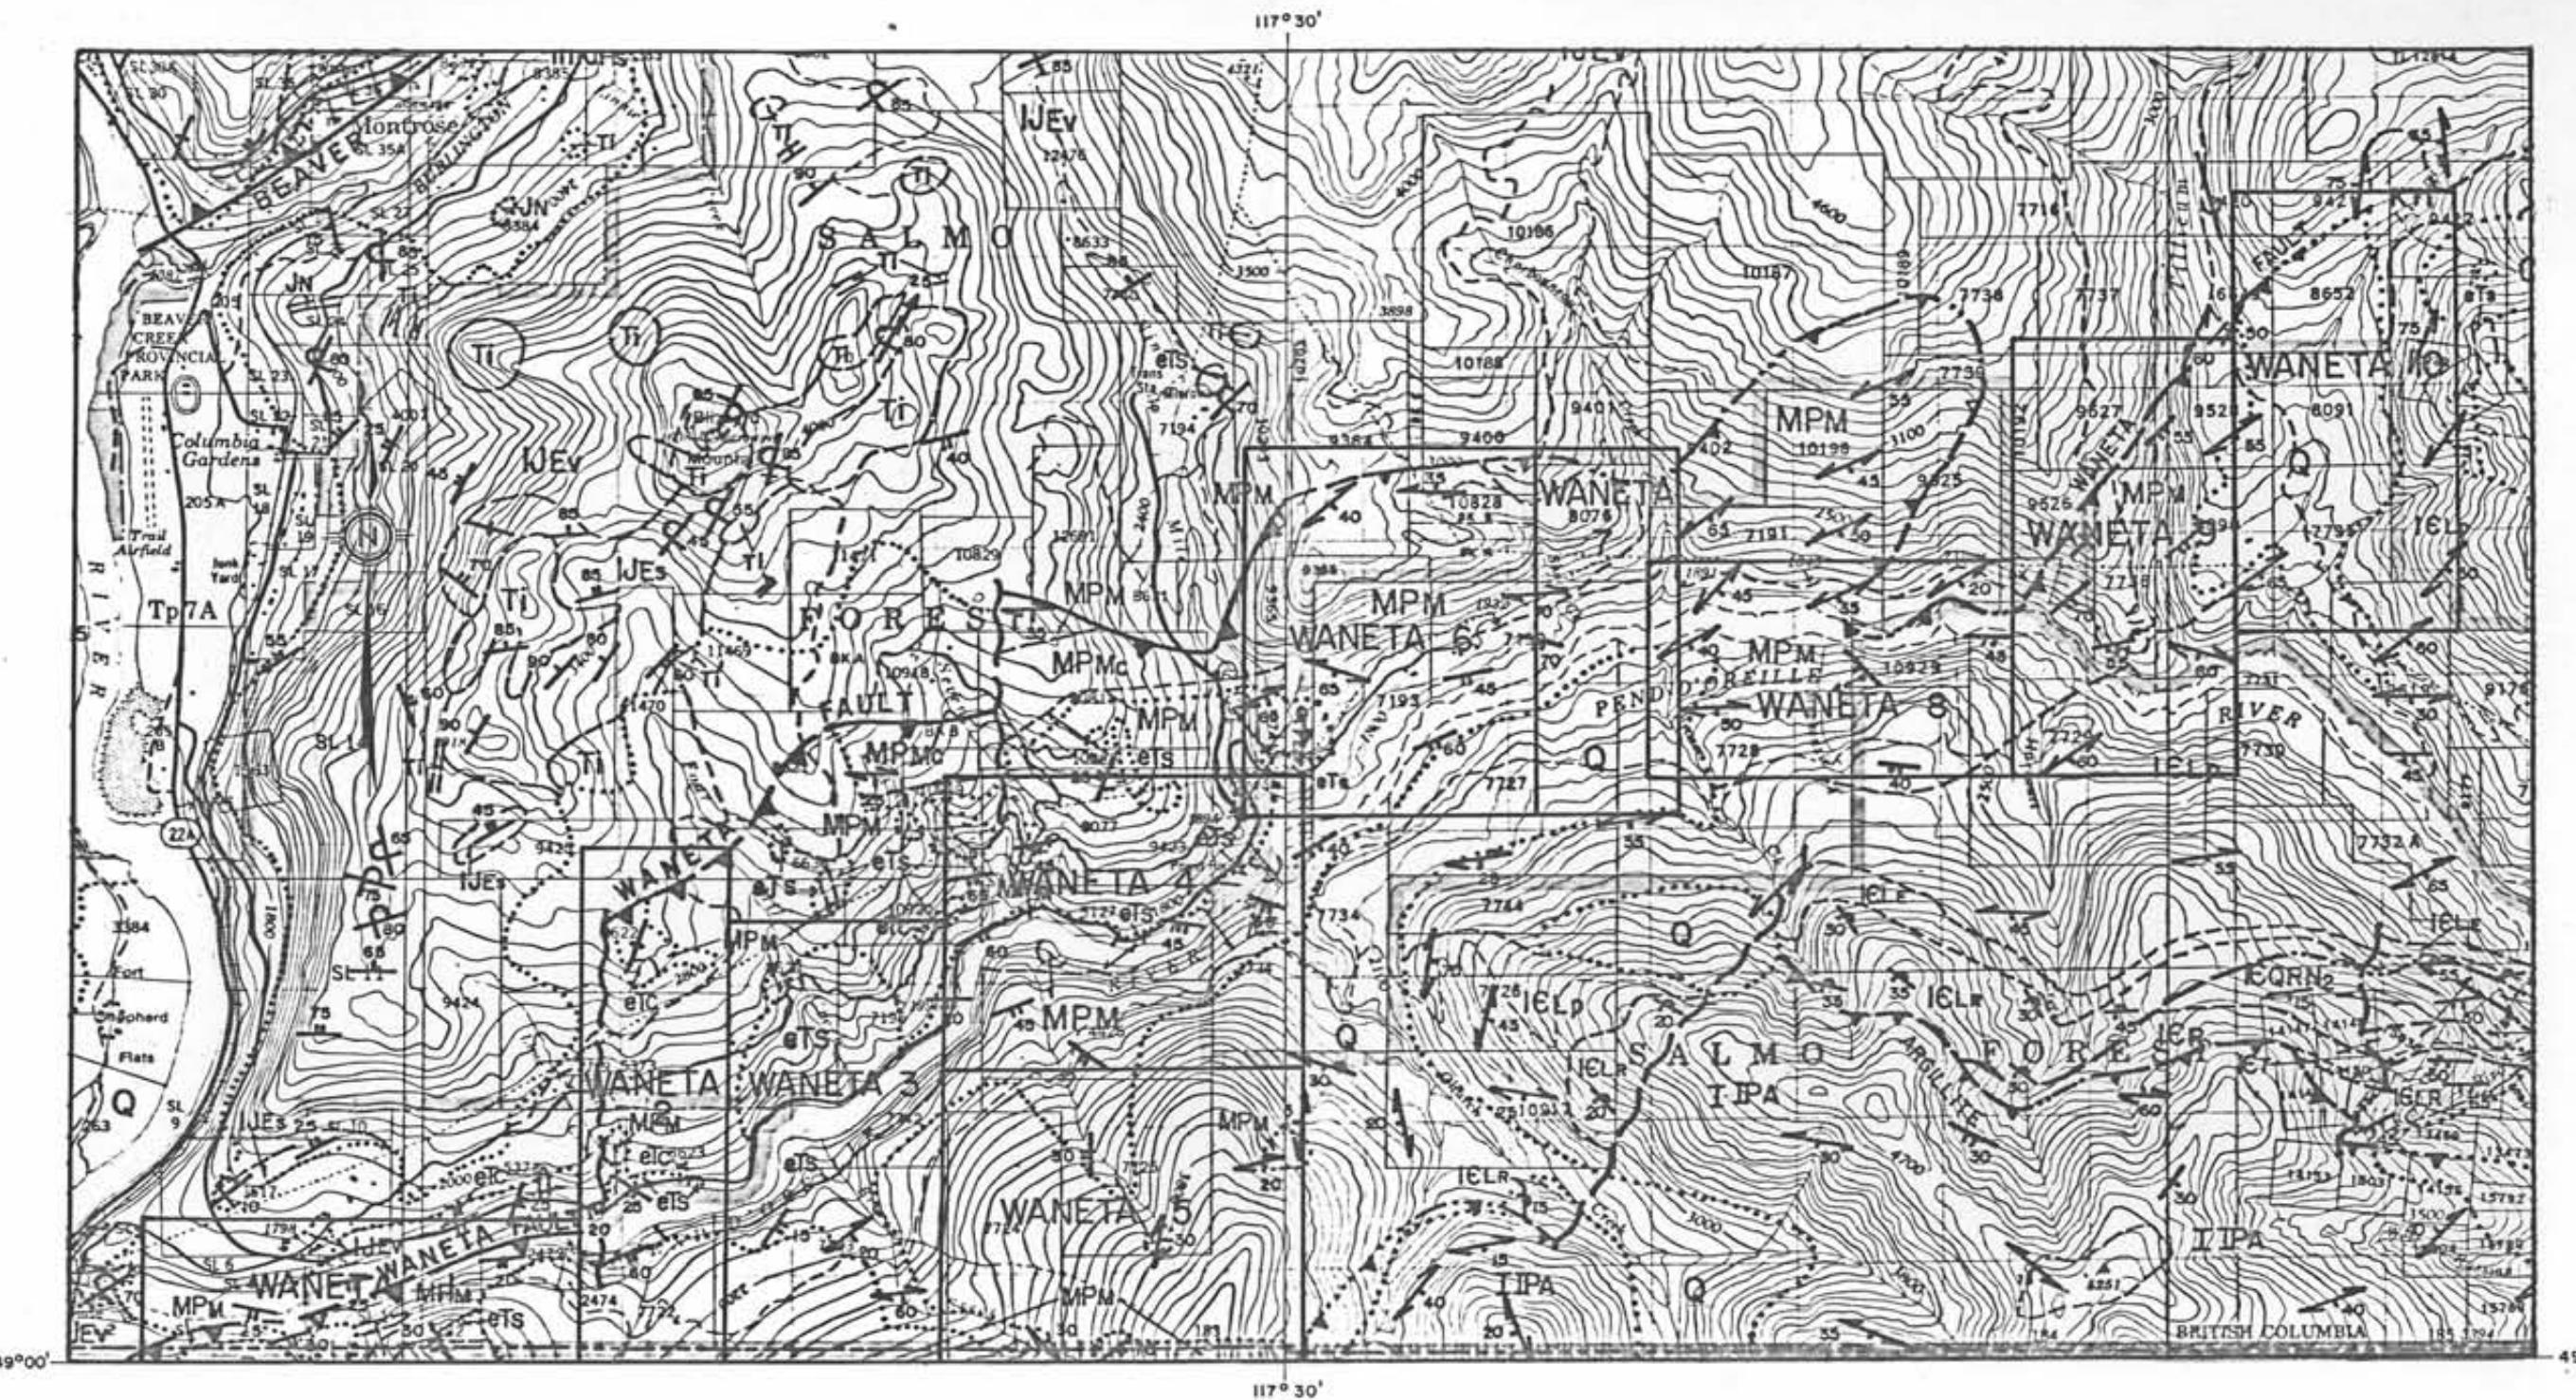

The property consists of ten mineral claims, the Waneta 1 to 10, all staked under the modified grid system and registered in the name of Rex Silver Mines Ltd. The claims are indicated on Figure 1.

Areas excluded from Waneta Claims
due to pre-existing mineral claims in
good standing

		(4,125 hectares)		

The Waneta 6, 7, 8, 9, and 10 mineral claims overlap several mineral claims which are currently in good standing. These areas have been excluded from the Waneta claims, and are depicted on Figure 1 by hatchured pattern.

Physiography and Glaciation

The claim group is located within the Bonnington Range of the Selkirk Mountains region of the Cassiar-Columbia Mountains physiographic province.

The southern part of the range, where the claims are situated, is underlain by volcanic rocks and is characterized by heavily forested mountains of relatively subdued relief, in contrast to the severe topography of areas to the north, underlain predominantly by granitic rocks.

Evidence of peneplanation can be seen throughout the region and it would appear that at least two stages occurred.

The topography of the area has been considerably influenced by Cordilleran glaciation with evidence of glaciation in the form of transported material found everywhere. The movement of the glacial ice has been recorded by many measurements of glacial striae and a few of roche moutonée. In all cases, the direction of ice movement was southerly.

Much of the claim group is overburden covered overlying wooded rounded hillslopes cut by a number of deep V-shaped stream valleys. Numerous small outcrops occur throughout the property north of Pend D'Oreille River with road cuts providing excellent bedrock exposures but those portions of the property which lie south of the river are more thickly wooded, with outcrops practically non-existent. Elevations on the claims vary from 518 m (1700') along Pend D'Oreille River, to 1340 m (4400') on the hills.

The climate of the district is pleasant with moderate winters and fairly hot summers. Snow has usually almost entirely disappeared by the first of June any does not interfere with prospecting until late October.

Land suited to agriculture is confined to small areas in the valley lowlands scattered throughout the property.

REGIONAL GEOLOGY

In the area, a belt of Carboniferous rocks forms a zone of discontinuous overthrust plates which rest mainly upon the Lower Jurassic andesitic Elise Formation (IJ_{ev}) of the Rossland Group 'arc type' volcanic rocks. The Carboniferous rocks are considered to be correlatable with the Mississippian-Pennsylvanian Milford Group (MP_M) and consist of black argillite, calcareous argillite, slate, phyllite, and grey-weathering black limestone. A thick bed of massive white to light blue-grey limestone (MP_{M_c}) is also present in the section and forms a distinctive marker horizon. The main trace of the thrust is offset, in a left-lateral sense, at several places by Tertiary faulting. Numerous small granitic plugs and cupolas(?) of Tertiary age intrude both the lower and upper thrust plates.

The regional geology is indicated on Figure 2. Table I summarizes the geological stratigraphy of the area.

Table I. Table of Formations

FRA	PERIOD OR EPOCH	GROUP OR FORMATION	MAP SYMBOL	LITHOLOGY	THICKNESS (metres)
CENOZOIC	QUATERNARY			Till, sand, gravel, silt	
		Coryell Intrusions	eTc	Syenite, quartz monzonite; minor granite, palaskite, and biotite-augite monzonite	
	EOCENE Middle			INTRUSIVE CONTACT

BASE NOT EXPOSED					

PROPERTY GEOLOGY

The property geology is illustrated on Figure 2 and on the accompanying four geology and traverse maps depicting the work completed on the property. A brief review of the underlying geology follows.

Carboniferous rocks (Milford Group equivalents) underlie the Waneta 1 claim south of Pend D'Oreille River in apparent thrust contact with underlying andesites of the Elise Formation which is exposed north of Pend D'Oreille River. Numerous north-south shears transect these andesites. The main trace of the Waneta thrust fault, which here coincides approximately with the course of Pend D'Oreille River, is offset in a left lateral sense along the western edge of the Waneta 2 claim.

The Waneta 2 to 7 claims, most of the Waneta 8 claim, and the central portion of the Waneta 9 claim are underlain by black argillites (interbedded with chert, quartzite, and phyllite), and white to light blue-grey limestone of Carboniferous age. These have been intruded by numerous granitic plugs and dykes of the Coryell and Sheppard intrusives.

The area south of Pend D'Oreille River is underlain by Carboniferous greenish-brown phyllites and black argillites and green phyllites of the Upper Laib Formation, which extends east of the Waneta 5 claim, and underlies the southern portion of the Waneta 9 claim and most of the Waneta 10 claim. Very siliceous and pyritic zones were found within this area.

Andesites of the Elise Formation underlie the northern part of the Waneta 9 claim and the northeastern part of the Waneta 8 claim, where a splay of the Waneta fault occurs.

ECONOMIC GEOLOGY

The spatial coincidence of overthrust rocks containing multiple carbonate horizons (interbedded with relatively impermeable slates and argillites) and numerous small Tertiary intrusives presents a geological setting favourable for the development of replacement and disseminated type gold mineralization.

Small quantities of placer gold have been produced intermittently from the gravels along the lower reaches of Pend D'Oreille River, and numerous placer occurrences are known along Columbia River, downstream from the mouth of Pend D'Oreille River.

This placer gold is evidently derived from within the property although only two lode occurrences are documented in the area: (1) the Blue Star adit, located in the centre of the Waneta 9 claim; and (2) the Bunker Hill workings, located on the eastern edge of the Waneta 10 claim. No production was recorded from either of these occurrences. Considerable work was completed at the Bunker Hill prospect in which, from all reports, the gold values were very low and erratic.

EXPLORATION APPROACH - 1983 FIELD PROGRAM

An extended research study of southern British Columbia identified a geological setting with good potential for disseminated gold mineralization in the area of the Waneta claims.

The spatial coincidence of a 'eugeosynclinal' assemblage of volcanic and sedimentary rocks (containing multiple carbonate horizons interbedded with relatively impermeable slate and argillites) overthrust onto a 'miogeosynclinal' carbonate succession and numerous small Tertiary intrusives is considered to present a geological setting favourable for the development of replacement and disseminated type gold mineralization. The presence of placer gold along that section of Pend D'Oreille River which drains the area of the Waneta claims suggests the possible presence of disseminated gold mineralization which may have gone undetected by earlier exploration efforts.

The exploration approach employed was intended to delineate the underlying geology of the property and to identify areas containing potential replacement and disseminated gold mineralization, and to examine in greater detail any such potentially mineralized areas.

Two small grids were placed, one on either side of the placer gold producing reaches of Tillicum Creek. Semi-reconnaissance ground VLF-EM and soil sampling surveys were carried out over the grids. A total of 8.2 line km of 25 m x 200 m grid lines were sampled and surveyed. All the grid lines were flag-and-compass lines.

Detailed prospecting of a chert-carbonate horizon and siliceous schists and phyllites was carried out on the property. Stream silt samples were collected from the numerous streams draining the property. The Blue Star occurrence and the Bunker Hill mine were briefly examined to determine the significance of this style of vein type mineralization with respect to the current exploration program.

GEOCHEMICAL SURVEY

Two small soil sampling grids (totalling 7 line km of cross lines and 1.2 line km of base line) were placed one on either side of the placer gold producing reaches of Tillicum Creek over an area underlain by a narrow pyritic chert horizon interbedded with massive carbonates. The grids were extended to cover the strike extension of the Blue Star occurrence to establish a comparative data base for the geochemical results.

A total of 334 soil samples were collected. The samples were analyzed by TerraMin Research Labs Ltd. in Calgary, Alberta for gold, silver, arsenic, and antimony. These analytical results are included in Appendix B. A series of maps (7 to 10) have been contoured for each of the elements at a scale of 1:2500.

A number of features are immediately evident from the contoured analytical results. The most obvious of these is the different geochemical signatures from the East Grid as compared to the West Grid. The East Grid is relatively quiet geochemically, whereas the West Grid has a number of east-northeasterly trending Au, Ag, As, and Sb anomalies.

East Grid

On the East Grid, one sample returned a gold value of 274 ppb from L4+00E, 2+25N. This site was associated with a weak east-west trending arsenic anomaly and an enriched silver zone immediately to the south.

Another soil sample, collected at L6+00E, 1+50S, is moderately anomalous in gold along a weakly developed east-west trending zone. There are no corresponding anomalies in other elements.

West Grid

The West Grid has a number of east-northeasterly trending coincident Au/Ag/As zones. The gold and arsenic values outlined discontinuous weakly

anomalous trends. However, the silver geochemistry outlined a strong northeasterly trending zone, open in both directions, in close proximity to the Blue Star adit. This zone warrants closer inspection to determine its significance.

The antimony results, on the whole, were very low, with only two geochemically anomalous areas delineated. One of these is a single sample site anomaly located on the base line at 5+75W (16.6 ppm Sb), with corresponding very anomalous arsenic and silver and weakly anomalous gold values. This anomaly is in close proximity to the plane of a thrust fault on the Waneta 9 claim. The second area is an east-northeasterly trending zone with values up to 8.9 ppm Sb, extending weakly across the grid. This zone corresponds very well with the previously mentioned silver anomaly. These areas should also be re-examined.

VLF-EM SURVEY

A VLF-EM survey was completed over the two grids using a Crone Radem unit employing Cutler, Maine, as the transmitting station. The survey was carried out using a 25 m station interval along the grid lines. The results are presented in profile format on Map 5 and in Fraser-filtered contour format on Map 6.

The interpretation of the VLF-EM data was complicated by the strong field effects of powerlines which cross the property. These field effects would have masked any geological conductors existing under and up to at least 100 m on either side of the powerlines. Any conductors occurring beyond this limit should be "real".

A number of northwesterly trending conductors were delineated on the West Grid, paralleling the powerlines. These conductors swing east to northeast on the East Grid. There is no correspondence between these conductors and the geochemical trends delineated. The conductors could be outlining geological contacts of the underlying interbedded argillite and limestone.

GEOLOGICAL MAPPING, PROSPECTING
AND STREAM SEDIMENT SAMPLING

Geological mapping and prospecting of the claim group confirmed the underlying geology of the property as shown on G.S.C. Map 1144A and outlined a zone of strongly pyritized siliceous gneiss which underlies the Waneta 10 claim. Samples were collected from this zone as well as from other pyritic areas and quartz veining. These samples were forwarded to TerraMin Research Labs Ltd. in Calgary, Alberta, for assay for gold, silver, lead, zinc, and copper, with the results presented in Appendix B and sample descriptions presented in Appendix A. The assay results were negative.

Grab samples were also collected from the Crown-granted Blue Star adit, located in the centre of the Waneta 9 claim and from the Bunker Hill mine, located on the eastern edge of the Waneta 10 claim. The sample collected from the Blue Star adit returned 422 ppb Au (0.012 oz/ton).

All streams encountered during traverses were sampled and analyzed for gold, silver, antimony, and arsenic. Sample CA-W-13, adjacent to a northerly striking fault on the Waneta 2 claim, returned an anomalous value of 102 ppb Au. The source area of the silts from this creek should be examined in greater detail.

CONCLUSIONS AND RECOMMENDATIONS

During the period July 22 to August 4, 1983, a total of thirty man days of exploration were carried out on the property. Reconnaissance work consisted of prospecting, stream sediment sampling, and reconnaissance geological mapping. In addition, a total of 8.2 line km of semi-reconnaissance ground VLF-EM surveying and soil geochemical sampling were carried out at 25 m station intervals along 200 m spaced lines over two small grids situated one on either side of Tillicum Creek.

The VLF-EM survey delineated a number of northwesterly trending conductors on the West Grid. Conductors swing east to northeast on the East Grid. No correspondence exists between the conductors and the geochemistry. The geophysical results could be interpreted as representing geological contacts of the underlying sedimentary rock units.

The soil survey outlined two very strong northeasterly trending silver zones as well as a number of discontinuous gold and arsenic zones. Coincident As/Ag/Sb geochemical anomalies occur in the far western part of the grid area in close proximity to the plane of a thrust fault on the Waneta 9 claim. These areas should be re-examined to determine their significance.

Reconnaissance mapping and prospecting of the property confirmed the underlying geology and outlined a strongly pyritized zone within a siliceous gneiss.

Silt samples were collected from the numerous streams draining the property. One of these samples, located adjacent to a northerly striking fault on the Waneta 2 claim, returned an anomalous gold value. The source area of the silts from this creek should be examined in greater detail.

It is recommended that a short program be initiated to examine those areas mentioned, i.e., the area to the north of the anomalous stream silt sample, the anomalous silver zones, the anomalous antimony sample sites on the West Grid, and the gold anomalies on the East Grid, as well as further prospecting of the pyritic zone outlined within the siliceous gneisses. All streams draining the property should be systematically sampled at 100 m intervals.

Sample Descriptions

<u>Sample</u>	<u>Description</u>
W-3-1	Massive grey fine-grained granite, pyritic. Numerous epidote stringers along fracture surfaces, occasional stringers of specular hematite; occasional 30-90 cm wide Bi-Feld porphyry basalt dykes.
CA-9	9 m wide shear zone, bearing 300°, schistosity 290-300°; contains narrow asbestos stringers and quartz veins; shear zone occurs in metavolcanics.
CA-27	Lt.grey and black banded siliceous phyllite to gneiss. Numerous quartz bands parallel to foliation. Large pyrite cubes disseminated throughout the quartz and the phyllite, mainly in the phyllite. Strike 22°, dip 69°E. East end of outcrops strikes 300°, dips 40°SW, occasional quartz veins up to 30 cm wide.
CA-29	Blue Star adit. 1.8 m wide shear zone containing chert and numerous narrow quartz stringers disseminated with pyrite; occasional 1 cm wide bands of massive pyrite. Country rock black to green argillite, striking 330°, dipping 30°SW. Adit is 6 m deep x 4.5 m wide x 4.5 m high. Shearing, same dip and strike as the bedding.
CA-19	Massive bluish white syenite containing disseminated pyrite, in contact with thin bedded argillite.
CA-30	Calcareous greenish-grey pyritic greenstone, sheared.
CA-31	1.2 m wide massive quartz vein, contains minor pyrite; in greenstone (CA-30).
CA-35	Black to brownish-grey siliceous pyritic argillite, striking 200°, dipping 65°E.
CA-38	Lt.grey limestone, containing narrow black bands, minor disseminated galena along fracture surfaces and black bands.
CA-39	30 cm wide quartz vein with disseminated pyrite (at CA-27 location).
Bunker Hill	grab samples from dump. Massive white quartz with large pyrite cubes, slightly carbonaceous, in sheared phyllites and gneisses.

BUNKER HILL

This group consists of two Crown-granted claims, Bunker Hill and Mormon Girl, both of which have reverted to the Crown. The workings are on the east side of Limpid (Sixteenmile) Creek at an elevation of 3,800 feet and have been abandoned for over thirty years. A road was built from Waneta on the Columbia River, up Pend-d'Oreille Valley, and to a point on Limpid Creek 1,000 feet below the workings. A stamp mill was constructed here and connected by tram to the workings.

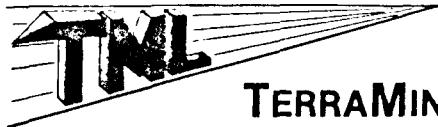

A quartz vein, striking approximately 40 degrees and dipping 45 degrees southeast, cuts impure quartzitic rocks of the Reno formation close to a granitic tongue at an elevation of 4,200 feet. The quartz vein is quite irregular.

Two adits have been driven presumably to tap the quartz vein. The upper adit is inaccessible, and the lower is partly filled with water and muck. The lower adit, 400 feet below the outcrop, intersects a quartz vein at 170 feet from the portal. This vein is possibly the downward continuation of the one outcropping. The vein in the adit strikes about 30 degrees, dips 45 degrees southeast, and closely follows the strike and dip of the impure quartzites. The vein at a point a few feet east of where it is entered is faulted 35 feet to the north. The vein has been followed for 80 feet east of the fault. A raise on the west side of the fault is about 25 feet high. The vein is composed of rather glassy quartz, some country rock, and a little pyrite. It has a maximum exposed width of 5 feet. There is no available record of the gold values, but from all reports the values were very low or lacking.

Analytical Techniques
and
Personnel

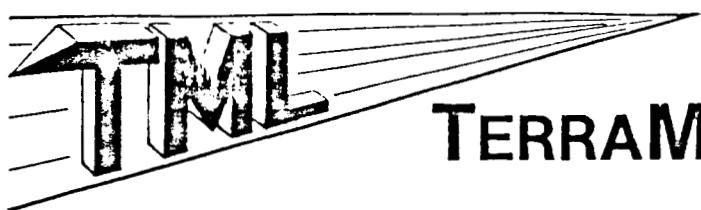

TERRAMIN RESEARCH LABS LTD.

14-2235 - 30th Avenue N.E. Calgary, Alberta T2E 7C7
(403) 276-8668

SAMPLE PREPARATION

Soil and sediment samples are dried and sieved through 80 mesh nylon screen (maximum particle size 200 microns).

Rock or drill core samples are crushed to approximately 1/8" in a jaw crusher, riffled to obtain a representative sample, and pulverized to 100 mesh (180 micron particle size).

(403) 276-8668

FIRE ASSAY/AA METHOD FOR GOLD AND SILVER PLATINUM AND PALLADIUM

Approximately 1 assay ton of prepared sample is fused with a litharge flux charge to obtain a lead button. The button is cupelled down to a precious metal prill which is then dissolved in aqua regia. The resulting solution is analysed by atomic absorption spectrophotometry to determine the precious metals.

TERRAMIN RESEARCH LABS LTD.

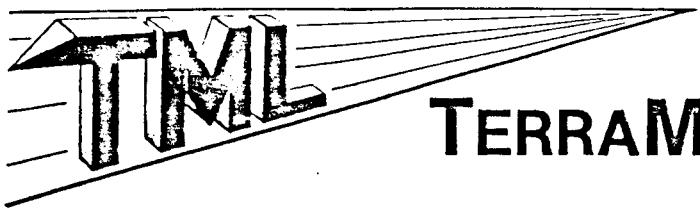

14-2235 - 30th Avenue N.E. Calgary, Alberta T2E 7C7
(403) 276-8668

ANALYTICAL METHODS FOR BASE METALS

Cd, Cr, Co, Cu, Fe (soluble), Pb, Mn (soluble), Mo, Ni, Ag, Zn

A portion of the prepared sample is digested in hot nitric/perchloric acid mixture, or hot aqua regia (nitric/hydrochloric acids).

Elements are determined by atomic absorption spectrophotometry.

TERRAMIN RESEARCH LABS LTD.

14-2235 - 30th Avenue N.E. Calgary, Alberta T2E 7C7
(403) 276-8668

ANALYTICAL METHOD FOR ARSENIC AND ANTIMONY

A portion of the prepared sample is digested in acid at low temperature. As and Sb are determined with a vapour generation accessory with atomic absorption.
