UNDERGROUND DIAMOND DRILLING, GEOLOGICAL MAPPING, AND SAMPLING KOOTENAY BELLE PROPERTY SHEEP CREEK CAMP NELSON MINING DIVISION SALMO, B.C. NTS 82 F/3 E LATITUDE 49°08', LONGITUDE 117°08'

SUMMARY

Exploration by underground diamond drilling, geological mapping and channel sampling began in February 1983 in the Hideaway, Vancouver and Kootenay Belle workings of Amore Resources Inc. The gold property is located in the Sheep Creek District of southeastern British Columbia, Nelson Mining Division, 16 km (10 miles) southeast of Salmo. Drilling from the Hideaway adit encountered the down-dip projection of the Vancouver vein but failed to intersect ore grade material over mineable widths at this level. Sampling of the Lower Vancouver adit has encountered 32 m (105') of vein grading 0.497 oz Au/ton across 0.73 m (2.4'); evaluation by drilling or by internal shaft to develop tonnage and grade is required. Encouraging assays have been obtained on the "B" and Black veins on 3 level of the Kootenay Belle workings; potential ore could be present above and below 3 level. Property holdings of Amore Resources Inc. in the Sheep Creek camp also include the Yellowstone and Dixie mines, both former gold producers. All of the foregoing deposits are expected to contribute tonnage to a cumulative production.

An exploration and development programme in six stages is recommended, the total cost of which is estimated to be approximately $2,000,000.

LOCATION AND ACCESS

The Amore Resources Inc. property is located in the Sheep Creek mining camp, 45 km (28 mi) east of Trail, B.C. and 16 km (10 mi) north of the Canada-U.S.A. border. The claims lie in the eastern half of NTS map sheet 82 F/3, near latitude 49°08'30" north, longitude 117°07' west, Nelson Mining Division, B.C. Elevation of the property ranges from 939 to 1524 m (3080-5000'). Access to the camp is by gravel road 9.6 km (6 mi) up the Sheep Creek valley from a paved road at a junction 6.4 km (4 mi) south of Salmo, B.C. The Yellowstone claims lie at the confluence of Waldie (Wolf) and Sheep creeks. Roads lead from here to the Kootenay Belle 6 and 3 levels, and to the Hideaway adit.

HISTORY

Mining in the Sheep Creek camp began in 1899 and continued to 1916. The second period of production began in 1928 with discovery of the Reno vein. Shortly thereafter, as gold mining became more profitable, former producers, the Kootenay Belle and Queen, together with the Gold Belt were equipped with modern mills. Production peaked in 1937 and was maintained at more than 135,000 tons/year until 1942. Only Sheep Creek Gold Mines remained a producer until 1951, after which only a small amount of gold has been produced.

A reported production of 1,721,580 tons containing 736,015 oz Au, 364,793 oz Ag, 377,000 lb Pb and 312,000 lb Zn has come almost entirely from ore shoots in quartz veins cutting folded Lower Cambrian and Precambrian (?) quartzites. Past production from veins on the Amore Resources property include:

Vein	Tons	Contained oz Au	oz Au/ton
"A"	204,000	84,300	0.413
"B"	32,000	9,150	0.286
Black	45,000	15,475	0.343
Dixie-6600	33,000	11,725	0.355
Yellowstone	27,000	5,600	0.329
Vancouver	350	960	2.743

(Matthews, BCDM Bull. 31, 1953, p. 52)

Totals	331,350 tons	127,210 oz Au

Averaging 0.384 oz Au/ton

CLAIMS

The following claims comprise Amore Resources Inc. holdings at present.

Present holdings = 19 claims totalling 405.93 acres.

INTRODUCTION

In February 1983, a programme was launched by Amore Resources Inc. to explore the Kootenay Belle property in the Sheep Creek Mining Camp, Salmo, B.C. The first exploration phase entailed underground diamond drilling from the Hideaway adit to test for down-dip extensions of the Vancouver vein.

Following clearance of snow from about 6 miles of access road and construction of a timber bridge across Wolf Creek, the drilling equipment was moved onto the property beginning February 15. Washing, mapping, sampling and surveying of the Hideaway adit commenced shortly thereafter and was completed by March 2. Pin holes were drilled and about 367 m (1200') of 10 cm (4") diameter air pipe was installed prepartory to commence-

ment of drilling on March 1. The mobile office was moved from 6 level Kootenay Belle portal to serve as a dry on the North Side of Wolf Creek near the Hideaway portal. Underground mining necessary to prepare drill stations consisted of slashing the walls and back and levelling the muck on the drift floor with a scraper.

During the period March 1-May 6, six diamond drill holes were completed, five flat and one of which was inclined at +70° for a total of 462.7 m (1517.5'). Numerous delays were caused by drilling equipment failure, and by unusual mud slides due to heavy rain on the Sheep Creek access road. Since the driller's performance was unsatisfactory and additional drill targets could not be immediately identified, the drill was released on May 6.

A rough 4x4 trail was constructed about one-third of the way to the Lower Vancouver adit before encountering rock obstacles. Timber and pumps were packed the remaining distance to the portal to permit rehabilitation and dewatering of the Lower Vancouver adit and underhand stopes. Mapping and sampling of the stopes and adit were completed by May 14. Coincident with this work, back sampling was undertaken on the "B" and Black vein within 3 level in the Kootenay Belle mine.

All core was split and analysed geochemically. All channel samples were also analysed for a suite of elements comprised of Au, Ag, Cu, Pb, Mo and As. Semi-quantitative spectrographic analysis was done on selected drill core samples and several channel samples. Check sampling and assaying were completed in early July. Sampling is continuing on the Yellowstone vein and is planned for the Dixie vein in August.

GENERAL GEOLOGY

Gold production in the Sheep Creek camp has come almost entirely from oreshoots in quartz veins which cut folded quartzites that are part of a thick succession of Lower Cambrian and Precambrian (?) sedimentary rocks. Folding took place prior to intrusion of several stock-like granitic bodies, an elongate swarm of quartz porphyry sills, and by numerous lamprophyre

dykes. Two tight northerly-trending anticlines with an intervening syncline make up the major structures of the camp. The granitic bodies are believed to be older than the ore and most of the lamprophyres to be younger.

Several sets of faults are known but the northeasterly-trending, south-dipping set with coincident quartz veins is of primary economic interest. Veins occupying these fissures consist of quartz with minor amounts of pyrite and variable amounts of pyrrhotite, chalcopyrite, galena, sphalerite and gold.

The geological setting of the Sheep Creek camp is further described in the "Report on the Kootenay Belle Property" (September 1982) by Davidson. Matthews (BCDM Bull. 31, 1953) is the definitive and most comprehensive study of the geology and ore deposits.

ECONOMIC GEOLOGY

Hideaway Adit

Mapping of the Hideaway adit, located at 1072.6 m (3318') elevation on the east bank of Wolf (Waldie) Creek, was completed February 18 to March 2, 1983.

The mapping programme covered 497 m (1630') of drift and crosscuts in the Hideaway adit and entailed the collection of 121 rock chip samples. The following description of the geology is based on a traverse from the portal to the northeastern end of this adit.

At the portal, at an aplite dyke-argillite contact, the adit was driven along a quartz vein 8-13 cm (3-5") wide which locally contains up to 2% pyrite. A short back slash was taken on this vein where it is traversed by a biotite-lamprophyre dyke. For 61 m (200') the northeast-trending adit follows the poorly-defined vein or lead until it disappears, either becoming indistinct or because of faulting. Dark chloritic schist of the Lower Reno Formation is in contact with quartzite of the Upper Navada member of the

Quartzite Range Formation 149 m (490') from the portal. At 168 m (550') a north-trending crosscut follows the hangingwall of a feldspar-quartz porphyry dyke. A weakly mineralized shear zone, trending N 65°E 65°S is encountered at 213 m (70') in this crosscut. This shear is probably an extension of the portal vein and also part of the principal lead which is exposed in the main adit, 280.5 m (920') from the portal.

Quartzite, argillaceous quartzite, argillite schist and another feldspar-quartz-porphyry dyke are exposed in the main haulage way between 167.7m (550') and 214.9 m (705'). Pyrrhotite, pyrite, and chlorite in irregular quartz lenses are common but no northeast-trending lead is visible. However, the next 12.2 m (40') of the main adit and a southeast-trending crosscut display complex deformation and fracturing. The crests and troughs of folds are faulted and the beds are slightly displaced. The southeast crosscut trends in the direction of the plunge of one of these folds. Also exposed in the crosscut are north-trending fault zones, and the contact with quartzites of the Upper Nugget member. The quartzite beds trend N 75°E 67°E and can be correlated with beds exposed at 289.6 m (950') in the main adit.

From 280.5 m (920') to the face of the adit at 390.2 m (1280') a shear zone or lead is exposed in the back and in short raises driven on the fracture. In a few places along this length, quartz vein material and pyrite are visible. However, most of the lead is only slightly more than a single fracture which cuts massive grey to white quartzite. At 320.1 m (1050') a timbered raise extends upward on the lead 28.4 m (93') to a timber bulkhead with the 1.8 m x 3.7 m (6' x 12') face estimated to be another 5.4 m (18') up, for a total length of 33.8 m (111'). The average dip of this raise is about 74°.

Vancouver Adits

The Vancouver adits were driven on a N 80°E 62°-83°S-trending quartz-pyrite vein which is principally hosted in grey to white quartzite of the Upper Nugget member of the Quartzite Range Formation. Trend of the beds is generally N 5°E 70°E but local folding near the vein is common.

As can be seen from the Geology Map included in this report, the first 9.1 m (30') of the Lower Vancouver adit was driven in argillaceous quartzite which displays regularly alternating thin layers of argillaceous beds. These sediments belong to the Lower Navada member of the Quartzite Range Formation. The contact with the Upper Nugget appears conformable to bedding, both of which are overturned. The vicinity of the Lower Vancouver adit lies on the west limb of the eastern anticline as described by Matthews (1953). From 9.1 m (30') to 96.6 m (317') in the Lower Vancouver adit the vein crosscuts the generally massive quartzite of the Upper Nugget. Near 85.4 m (280') from the portal, crude correlation of massive white quartzite on the footwall (north wall) with similar quartzite in the hangingwall indicates that approximately 1.8 m (6') of right lateral displacement has taken place along the plane of the vein.

During reconnaissance in the vicinity of the Vancouver adits a previously undescribed adit was located 83.8 m (275') downslope S 10°W from the portal of the Lower Vancouver. The adit is 11 m (36') long, trends N 30°E, and crosses quartzite beds which trend N 10°E 70°E. The adit follows a 1 m (3') wide quartz vein for part of its length. The quartz is conformable with tan to white massive quartzite and appears deficient of sulphides.

Another adit located 64 m (210') N 64°W from the Lower Vancouver portal follows a shear zone for most of its 10.7 m (35') of length. Fault gouge is present in the fissure which trends N 75°E 72° southwest. It cuts phyllitic schist with lesser thin beds of argillaceous quartzite. Pyritiferous quartz vein material is present on the dump near the portal of this adit but only minor pyrite was seen in vein material from underground.

Approximately 61 m (200') N 30°W from the above described adit, also near the trail leading to the Lower Vancouver portal, a trench or pit exposes a fissure oriented N 55°E 55°S which crosscuts N 7°E 64°E-trending sedimentary beds of argillite and quartz. The fracture locally contains clay and quartz.

Kootenay Belle Level 3

During May and June 1983, sampling of the Black and "B" veins in 3 level of the Kootenay Belle was undertaken. Detailed geological mapping of the adit and drifts was not attempted at this time due to the generally muddy condition of the walls. However, quartzite similar to that in the Hideaway adit is present, particularly in the stoped areas on the Black vein and in drifts to the east. Dark green to black schists as seen in the Hideaway adit are not present in the drifts on the Black or "B" veins on 3 level.

On "B" vein, 3 level, 1+55' west, a zone of breccia was encountered. Angular fragments of quartzite to 0.25 m (10") are weakly cemented by clay. Walls and back are unstable and at 1+75 W the rubble completely blocks passage. The vein or lead in this zone is indistinguishable. Fault displacement along the plane of the "B" and Black veins could not be measured. Matthews (1953) however has computed net right lateral slip of the Black vein on 3 level to be 3.2 m (10.5') and two locations on "B" vein to be 7.9 m (27') and 14.6 m (48').

SAMPLING

Hideaway Adit

The Hideaway adit has been sampled at 1.5 m (5') intervals where vein material is exposed. Sampling began on February 22 and finished on February 28, 1983. One hundred and nineteen channel samples were gathered. In addition, several grab samples from muck in the timbered raise and four samples from the back slash area at M116+75E have been collected.

In general, a 0.3 m (1') channel across the vein or lead plus a sample of equal length on each of the hanging- and footwalls was collected. In areas where quartz was absent or sulphides were sparsely disseminated, footwall and hangingwall samples were not collected. Much of the Hideaway

adit between M104 and M115 does not follow the vein; in this area only pyritized or altered zones were sampled.

Five feet inside the Hideaway adit from the portal, quartz vein material contains 0.362 oz Au/ton and 0.20 oz Ag/ton. The vein is 7-10 cm (3-4") wide and has been back-slashed 3-4 m (10-12') high for a distance of 6.1 m (20') to sample #101+25E which returned 0.152 oz Au/ton and 0.27 oz Ag/ton across a 0.3 m (1') width. Of this 0.3 m (1') sample, 1/3 is lamprophyre (mafic) dyke, 1/3 white quartz vein, and 1/3 argillite. Significant gold values were obtained in the next three samples in quartz vein or altered argillite host.

M101+35E	0.91 m (3')	0.178 oz Au/ton	0.24 oz Ag/ton
M101+45E	0.67 m (2.2')	0.134 oz Au/ton	0.19 oz Ag/ton
M101+55E	0.6 m (2')	0.088 oz Au/ton	0.21 oz Ag/ton

The second anomalous area in the Hideaway adit includes three samples spaced 3 m (10') apart which begin with M102+153E at 67.1 m (220') from the portal. Each sample showed fractured and silicified argillite with varying amounts of pyrite, limonite and hematite.

M102+153E	0.6 m (2')	0.114 oz Au/ton	0.10 oz Ag/ton
M102+168E	0.6 m (2')	0.060 oz Au/ton	0.08 oz Ag/ton
M102+182E	0.4 m (1.3')	0.088 oz Au/ton	0.08 oz Ag/ton

The third and locally the strongest auriferous area occurs in the main drift approximately 305 m (1000') from the portal. At station M116+75V a 0.3 m (1') chip sample across quartz-pyrite-pyrrhotite vein material exposed in the back at the edge of an untimbered back slash assayed 1.702 oz Au/ton and 0.46 oz Ag/ton. A 0.91 m (3') chip sample on the footwall side of this vein assayed 0.046 oz Au/ton and 0.10 oz Ag/ton. The argillaceous quartzites in the hangingwall were barren. Four samples collected at 3 m (10') intervals on the portal side of the sample #M116+75V did show anomalous gold values. In this area the lead is poorly defined and is not coincident with quartz and/or sulphide veining. Anomalous values may occur on the hanging- or footwall side of the main fissure or fracture, and are as follows:

M116+65FW	0.79 m (2.6')	0.076 oz Au/ton	0.28 oz Ag/ton
M116+55FW	0.91 m (3.0')	0.050 oz Au/ton	0.13 oz Ag/ton
M116+45HW	0.84 m (2.75')	0.050 oz Au/ton	0.01 oz Ag/ton
M116+35FW	1.06 m (3.5')	0.090 oz Au/ton	0.19 oz Ag/ton

On the eastern side of the back slash sample M116+90E did not contain anomalous values.

In addition to the three main anomalous areas previously mentioned, three single-sample locations contained greater than 0.05 oz Au/ton. At station M120+54E, a select sample of quartzite with disseminated galena contained 0.062 oz Au/ton and 0.06 oz Ag/ton.

At station M106+0E a 1.2 m (4') chip sample of quartzite and schist near the hangingwall of a feldspar-quartz porphyry dyke contained 0.066 oz Au/ton and 0.07 oz Ag/ton. Pyrite and pyrrhotite are common in this area.

Lastly, at M107+12E at the intersection of a hangingwall split in the main fracture, quartz contained 0.066 oz Au/ton and 0.21 oz Ag/ton.

Lower Vancouver Adit

The planning to map and sample the underhand stope in the Lower Vancouver adit was revised when it proved impossible to build the access road due to budget constraints. Dewatering had to be undertaken with equipment light enough for men to pack in over the last 244 m (800') of footpath. Although this was slower, it was possible to pump water from the stopes to allow sampling.

Initial sampling of the first 24.4 m (80') of the Lower Vancouver adit was undertaken by James Logan in 1981; these data are compiled into assay plans which accompany this report. After the adit was pumped and timber and lagging replaced, geological mapping and channel sampling were started on May 5, 1983. The remainder of the 96.7 m (317') adit was mapped and samples were collected at 1.5 m (5') intervals. Hangingwall and footwall samples were taken where appropriate. Five samples were chipped from the vein in the underhand stope and seven channels taken from the upper

stopes. Sample locations in the Lower Vancouver adit are shown in a section and plan in the pocket of this report. Three small underhand stopes are depicted on the longitudinal section. The western underhand stope is partially caved and unsafe. The middle stope is joined at depth with the first stope but is too narrow to enter from above. The third underhand stope bottomed out 7 m (23') below track level. Fifty-seven samples were obtained from the Lower Vancouver adit during 1983.

Kootenay Belle 3 Level

"B" Vein

The "B" vein as exposed in the Kootenay Belle Mine 3 level has been sampled on 1.5 m (5') invertals from 47.3 m (155') west of the main crosscut to 132.6 m (435') east where "B" vein intersects the "A" vein. A major split in the vein fracture at 106.7 m (350') east, developed by a stub drift, was also sampled. To date 128 channel samples have been collected from the "B" vein. Locations with accompanying assay values are shown on a plan map in the pocket of this report. Areas of vein which contain 0.100 oz/ton gold or higher are discussed in the Grade Calculations section of this report.

A few areas of note within the "B" vein drift are as follows:

- at 30 m (1+00E) a 15 cm (0.5') zone on the south wall is weakly brecciated (?) and may represent a N 10°E 90° (?) fault.

- from 36.6-38.1 m (1+20-1+25E) the vein and immediate wallrock is moderately broken; manganese oxide and pyrite are present.

- at 60 m (2+00E) the vein changes direction from N 40°E to N 60°E and is coincident with an increase in FeOx, MnOx and pyrite. At 65.5 m (2+15E) 50 cm (2') of pyrite is visible; a light blue precipitate ($CuSO_4$?) occurs as secondary encrustations. Pyrite content of the vein zone decreases between 76.2-80.8 m (2+50 and 2+65E) but increases and is locally strong to the face of the stub drift southeast of 106.7 m (3+50E).

- at 100.6 m (3+30E) and 103.7 m (3+40E) hangingwall splits are not mineralized. However a split at 108.2 m (3+55E) is strongly mineralized with pyrite and has been explored by 14.3 m (47') of drifting. At 11.9 m SE (0+39SE) on the northeast wall of this stub drift, a 76 cm (2.5') wide white quartzite bed contains moderate stockwork pyrite veining. Preliminary observations suggest this pyrite zone may extend northward along the quartzite bed to its intersection with the main drift. Sample 11.9 m (0+39SE) assayed 0.070 oz Au/ton.

- from 108.2-132.6 m (3+55E) to 132.7 m (4+35E) on the "B" vein to the point where it diverges from the "A" vein, pyrite concentration within the quartz vein is generally 1-3% which is less than is present in the southeast stub drift.

- from 47.3 m W (1+55W) westward for an undetermined distance, a clay-quartzite breccia zone may postdate most shearing or quartz veining on the "B" vein. This is probably correlative with the caved zone on the "A" vein in the 6 level drift immediately to the east of the crosscut.

Black Vein

The Black vein as exposed in 3 level has also been sampled on 1.5 m (5') intervals for its entire length, except where previous mining has removed the vein. To date 118 samples have been collected on the vein and adjacent wallrock.

In the east drift from the 3 level crosscut, the quartz-pyrite vein is widest in the stoped area between 4.0 m (0+13E) and 19.8 m (0+65E). The vein is distinctive although narrower (<0.3 m) from 19.8 m (0+65E) to 27.4 m (0+90E) where the vein direction changes from N 75°E to N 50°E. From 27.4 m (0+90E) to the east face at 51.5 m (1+69E), the lead is often expressed by only a fracture. Quartz and traces of pyrite are sporadically distributed along this fissure zone. In the face of the east drift the lead trends N 80°E 67' S. At 38.1 m (1+25E) a southeast split into the hangingwall of the vein has been explored by a 18.9 m (62') stub drift. At 7.6 m (25') into the drift the lead disappears into the northeast wall. Five channel samples were gathered from this area.

The western drift on the Black vein is 93.0 m (305') long. A stope between 40.0 m (1+31W) and 55.2 m (1+81W) prohibited sampling in this area. Near the face of the west drift the main lead or vein splits and therefore two samples were collected. The splits each appeared weak and unmineralized.

"A" and Queen Veins

No attempt was made to sample the "A" vein on 3 level. The drift is caved 4.5 m (15') east of the crosscut, and open, poorly timbered stopes prohibit safe access to the west.

Two samples were collected from a stub drift to the east off the main crosscut approximately 293 m (960') from the 3 level portal. This drift follows a fracture containing vein quartz which is shown to be the Queen(?) vein on old maps, but does not continue far enough easterly to enter the favourable Lower Nugget Quartzites. Appreciable gold values were not obtained from these two samples.

Surface

On May 12, 1983, a brief geological reconnaissance traverse was made above and to the northeast, along strike of the Vancouver vein. A sample, labeled "Van Surface", was collected from the northeast face of the open cut overlying the Vancouver adit stopes. It represents 0.15 m (0.5') of quartz-limonite vein material which contains 3% pyrite and traces of visible gold. The face is nearly inaccessible. Foot- and hangingwall contacts are sharp. The sample is reported to have assayed 0.066 oz/ton Au but this value is questionable; therefore the station will be resampled.

Northeast of the open cut on surface, the sharp footwall contact can occasionally be seen in a bluff face as the lead is traced uphill. Near 1341.5 m (4400') elevation several prospect trenches dug in soils and rubble failed to locate the vein. No other prospects were seen on the projected trend of the vein. During traverses, a 1.5 m (5') deep prospect pit was

located at 1372 m (4500') elevation on the ridge overlooking Wolf and Sheep creeks approximately 45.7 m (150') northwest of the projected Vancouver trend. A 0.6 m (2') wide barren quartz vein parallels steeply dipping argillite beds.

Another 30.5-61 m (100-200') up the ridge towards Yellowstone Peak massive white weathered quartzite, probably belonging to the Motherlode Quartzite, is exposed. The lower elevations of these exposures were briefly examined but no prospects or transverse shear zones were found.

Northwest of the portal of the Lower Vancouver an adit is located slightly below the trail leading to the Lower Vancouver. Two samples were collected from this adit which is 10.7 m (35') in length. Sample LV+210NW is located in the adit 3.7 m (12') from the portal, and represents a 0.3 m (1') chip across argillite and fault breccia. The fault zone is 6 cm (0.2') wide with clay and limonite. No sulphides are visible. At a few places along the fault, minor amounts of vein quartz can be seen. However, no quantity of quartz-pyrite similar to sample LV+211NW collected from the dump was seen underground. The dump material contained up to 10% coarse-grained pyrite in white quartz vein material at least 15 cm (0.5') in diameter. Assays show LV+210NW to contain 3.35 oz Au/ton and LV+211NW to contain 1.08 oz Au/ton. From geological observation, the adit sample seemed unreasonably high; resampling obtained a value of 0.378 oz Au/ton. The fault-vein zone is important with respect to its projected location in the Hideaway adit level. Correlation will be discussed later.

Also described previously in the Economic Geology section of this report is an adit 11 m (36') in length located 82.3 m (270') S 10°W from the Lower Vancouver portal. Sample LV+270S is from a quartz vein 0.9 m (3') wide which is conformable to the quartzite beds. It did not contain detectable quantities of gold.

Underground Diamond Drilling

Contract diamond drilling from the Hideaway adit began with hole KB-83-1 on March 1 to test the Nugget Formation for an extension of the Vancouver vein. The hole size was reduced from BQ to AQ at 43.6 m (143') and then changed to IAX (standard) at 53.7 m (176') in an attempt to determine the most efficient approach in drilling the hard, abrasive quartzite formations. At 30.8 m (101.04') to 30.88 m (101.29') a 0.3 cm (0.01') sulphide veinlet assayed 0.348 oz Au/ton and 0.10 oz Ag/ton. Orientation and location of this veinlet suggests that it is the Vancouver horizon. The hole was continued to a total depth of 145.4 m (477') to prospect the quartzites to the southeast. Hole KB-83-2 was oriented to test the Vancouver vein at a point 30.5 m (100') to the west of this intersection (strike assumed NE to E). Hole KB-83-3 was drilled at +70° to test the vein at a point about 61 m (200') above the adit elevation. Holes KB-83-4 and KB-83-5 were oriented so as to intersect the vein along strike to the east and KB-83-6 was extended to test the vein 15.3 m (50') west of the initial intersection. A total of 462.7 m (1517.5') was drilled in six holes. Dip tests indicated that the holes wandered only an insignificant amount in the vertical plane. All core is stored on site in a locked semi-trailer.

GEOCHEMISTRY

General Statement

To date, 720 core and rock chip samples have been collected from the Kootenay Belle property. All samples have been analysed for copper, molybdenum, lead, arsenic, silver and gold. Loring Laboratories Ltd. of Calgary, Alberta, performed the analytical support. Their certificates of assay are included as an appendix of this report. As standard procedure, samples were first analysed geochemically by atomic absorption technique. Values of metals are quoted in parts per million except gold which is quoted in parts per billion (1000 ppb equals 1 ppm). If contained metal value is greater than 1000 ppm (or 1000 ppb for gold), fire assay technique is employed and base metals are quoted in percent and precious metals in ounces (troy) per ton (short).

Eight rock samples have also been analysed by semi-quantitative spectrographic method by Can Test Ltd. of Vancouver, B.C. Thirty-four elements are expressed in percentages for each sample.

Exploration during 1982 has been concentrated in four general areas: the Hideaway adit, diamond drilling from the Hideaway adit, Vancouver adits, and Kootenay Belle 3 level. The analytical data from these areas have been treated statistically by construction of histograms and probability graphs using cumulative frequencies and population percentages. For a population of 720 samples, the following statistics concerning trace metal levels have been determined.

Element	Threshold	Anomalous (2 x Threshold) (First Contour)	Strongly Anomalous (4 x Threshold) (Second Contour)
Arsenic	8.5 ppm	17.0 ppm	34 ppm
Lead	107 ppm	214 ppm	428 ppm
Copper	12 ppm	24 ppm	48 ppm
Molybdenum	4.2 ppm	8.4 ppm	16.8 ppm
Silver	1.0 ppm	2.0 ppm	4.0 ppm
Gold	210 ppb(?)	420 ppb(?)	840 ppb(?)

Arsenic values range from 0 to 265 ppm. Of the population of 720 samples, 21.5% has values greater than a threshold of 8.5 ppm. Graphic distribution of values indicates two distinct populations. Greater than 17.0 ppm As represents anomalous samples of the smaller population.

Lead values range from 1 to 1600 ppm. Of the total population, 6.8% has values greater than 107 ppm (threshold). Cumulative frequency curves indicate two populations of lead. Anomalous samples (>214 ppm) account for less than 2.8% of the total population.

Copper values also appear to lie in two populations, with the division between the two near 12 ppm. Fifteen percent of all values are greater than 24 ppm. Range of copper concentration is between 1 and 1100 ppm.

Molybdenum values range from less than 1 ppm to 22 ppm. There is a distinct frequency of population change at 4.2 ppm, with 19% of the samples showing values greater than 4.2 ppm. Most of these come from the Hideaway adit.

Silver values range from less than 0.1 ppm to 16.0 ppm. Graphic representation of population frequencies indicates an inflection point at 1.0 ppm, suggesting two populations divide at the 43.4% mark. The smaller group has anomalous and strongly anomalous values of 2.0 and 4.0 ppm respectively.

The quantity of gold in 720 rock and core samples from the Kootenay Belle property ranges from less than 5 ppb (0.005 ppm or 0.005 grams/tonne) to 2.327 ounces per ton (79.8 ppm or 79.8 grams per tonne). For the most part the graphic depiction of cumulative frequencies indicates a single gold population if very high and very low values are disregarded. However, there are several subtle inflections which reflect weak frequency changes. The most distinctive of these changes occurs at 210 ppb (0.21 ppm). Of the population, 43.4% has values of greater than 210 ppb Au, which is notably similar to the silver threshold percentage. Another more subtle threshold change may occur at 1500 ppb, suggesting a third population. However, neither inflection at 210 ppb nor 1500 ppb is clearly indicative of more than one phase of gold mineralization. Therefore, the level of gold in any single sample may not be used to suggest proximity to higher grade mineralization or ore shoots.

Hideaway Adit Geochemistry

One hundred and nineteen rock channel samples have been gathered from the Hideaway adit. Quartz vein material, disseminated or vein sulphides and/or iron oxide disseminations or veins contained in the Lower Reno through the Middle Nugget quartzites are represented. In addition, 10 channel samples from raise areas above the adit were also collected.

Three distinct, multi-sample areas containing high gold values are present in the Hideaway adit. In the two areas nearest the portal (M101 through M102+91E), 13 samples contain greater than 0.3 grams/tonne gold (0.008 oz/ton). This vein, which varies from 0.09 to 0.91 m in width, also carries copper up to 0.11%, lead to 810 ppm and silver to 9 ppm (0.27 oz/ton). No appreciable Mo or As occur in this zone.

In the area of the highest gold values in the Hideaway adit, between M116+35 and M116+75, the vein is 0.79 m to 1.06 m wide and contains values greater than 1.7 grams/tonne (0.05 oz/ton). Samples collected at M116+75EV and at 0.76 m (2.5') intervals in the raise above assayed as follows:

Sample	Width	Assay	
M116+75EV	0.3 m (1.0')	58.4 gr/tonne	1.702 oz/ton Au
M116+2.5V up	0.3 m (1.0')	0.55 gr/tonne	0.016 oz/ton Au
M116+5.0V up	0.3 m (1.0')	17.9 gr/tonne	0.522 oz/ton Au
M116+7.5V up	0.3 m (1.0')	5.1 gr/tonne	0.148 oz/ton Au
M116+10.0V up	0.3 m (1.0')	1.4 gr/tonne	0.040 oz/ton Au

Undoubtedly comparable or higher grade material was extracted from the small back-slash. An inset on the assay plan map shows sample locations in the back-slash.

Arsenic is strongly anomalous in or near the 12 m (40') long gold mineralized zone between the back-slash at 116+25E and 116+75E. Values up to 183 ppm As are closely correlative with gold mineralization. Lead is nearly as distinctive in this zone: M116+65FW contained 340 ppm Pb and M116+75V contained 500 ppm Pb.

If background for molybdenum is considered to be less than 4.2 ppm for the entire Kootenay Belle property as calculated from probability plots, nearly every sample collected in the Hideaway adit would be anomalous. It is feasible that the veins and fractures in the Hideaway adit may have tapped a deep-seated hydrothermal source of MoS_2, i.e. a Cu-Mo porphyry stock, but it is also possible that an error in sampling or analytical procedures (calibration of atomic absorption unit) has caused elevated values. However, useful information is obtained if molybdenum values in the Hideaway adit are examined by themselves. Anomalous values of greater than or equal to 15 ppm Mo occur:

1) at M107+19 and M107+21. No appreciable gold was detected but Mo in this lead could be related to gold detected in sample M107+12 which is 2.7 m (9') away on the same structure.

2) at M106+8E, 18 ppm Mo occurs in a 1.2 m (4') section which is only 1.2 m (4') east of M106+0E which contained 0.066 oz Au/ton.

3) at M111+175E, 19 ppm Mo is contained in quartz vein material in the Upper Nugget.

4) at M120+25E and M120+70E, Mo up to 16 ppm occurs in the wall-rock and main lead but is not associated with anomalous gold.

5) at M106+30E, 20 ppm Mo is contained in quartz-filled gash veins in argillaceous quartzites.

In summary, molybdenum in the Hideaway adit is slightly elevated near but not within areas of anomalous gold. Neither is molybdenum restricted to cleaner quartzites or particular formations.

Silver does not appear to be a useful indicator or guide to gold mineralization. Values range from 0.02 ppm to 16 ppm. Only the very highest gold values seem to correlate with coincident high silver concentration.

Diamond Drill Hole Geochemistry

Trends of gold-bearing zones between drill holes are speculative. There is a suggestion that base metal values may occur in linears parallel to the Hideaway adit but gaps are obvious in some drill holes. In general, metal values are lower in the wallrocks as might be expected remote from the vein fractures. Molybdenum, in particular, may flank gold values in nearby fractures but does not necessarily occur in the same sample as gold. This may suggest more than one mineralizing event or opening of fractures which has overprinted one metallization upon another.

Details of metal provenances are provided in the Appendix.

Lower Vancouver Geochemistry

Significant gold values were obtained from channel sampling in the Lower Vancouver adit. Grade calculations are discussed later in this report.

Lead correlates moderately well with increased gold values. Copper and arsenic are sporadically coincident with gold, but molybdenum shows no significant increase or zoning with respect to gold.

In addition to the calculated gold grade in the stope area, very high geochemical amounts of gold were received from samples between 2+10E and 2+75E. Six of 14 samples contained greater than 0.03 oz Au/ton, with a high of 0.184 oz Au/ton at 2+75' east.

Kootenay Belle 3 Level Geochemistry

Gold mineralization occurs along vein exposures and stoped areas of the Black and "B" drifts of the 3 level Kootenay Belle Mine. The potential ore zones are discussed later in this report.

Lead and silver appear to correlate moderately well with high gold values, often showing anomalies of 20 times background. Copper and arsenic show weak signs of correlation with gold, but tend to be more erratic in distribution than lead or silver. Molybdenum values are generally very low (1-3 ppm) and not correlative.

Summary of Geochemistry

In summary, the quantity and distribution of lead in the drifts and underground diamond drill holes is more often associated with gold mineralization than are other base metals. Copper and arsenic occasionally demonstrate increased geochemical values in areas of gold mineralization but their distribution is sporadic and not as consistent as lead. Molybdenum only showed local increases in the Hideaway adit and diamond drill holes. Its distribution locally demonstrates a halo-type pattern with respect to gold. Molybdenum appears to show higher concentrations in the southern part of the property which may reflect a source either toward the south or at greater depth. Silver geochemistry is restricted to a narrow range of values and area of distribution. Its use as a pathfinder to gold is severely limited.

These statistical and spatial characteristics will be of value in analysing the significance of geochemical results from soil sampling. If further drilling or drifting is undertaken, geochemical patterns may be used to guide the exploration. A M.Sc. Thesis by Tessari (U.B.C., 1979) developed empirical guidelines from relative metal contents for use in the United Keno Hill mines. The predictive model can assign a sample to (in effect) a location within a zoning pattern in the plane of a vein, and thence suggest the direction which development headings should take to encounter an ore shoot. This type of analysis should be considered for treatment of the geochemical data accumulated to date.

GRADE CALCULATIONS

Vancouver Vein - Lower Vancouver Adit

Assays from detailed sampling of the Lower Vancouver adit between 18.3 m (60') and 50.3 m (165') from the portal, a length of 32 m (105') of vein having an average width of 0.73 m (2.4'), contains a weighted average grade of 0.497 oz Au/ton. Appreciable values of gold are hosted in wall-rocks which may be included in mining widths. This section may have been partially mined to approximately 7.0 m (23') below track level, but appears to be more systematically mined overhead to surface.

"B" Vein - Underground Sampling

In the "B" vein on 3 level, channel samples of 0.3 m (1') of vein at 1.5 m (5') intervals indicate the vein averages 0.163 oz Au/ton over a distance of 32 m (105'). This section begins 62.5 m (205') east of the main crosscut. At a point 109.8 m (360') east from the main crosscut this sampling approach has indicated a vein length of 13.7 m (45') to the east averaging 0.117 oz Au/ton across 0.3 m (1') of width.

This may have implications for potential ore tonnage inasmuch as old mine records show this vein was not mined for 100.6 m (330') up to No. 2 sublevel. In addition, no mining on this vein took place below 3 level, so that considerable potential for ore tonnage may exist.

Black Vein

Sampling on the 3 level drifts on the Black vein has indicated a first approximation of grade tenor to be expected in any remaining ore that might be found in this vein. The average grades derived herein for the Black vein can be considered low because former mining operations removed sections within the lengths sampled which were undoubtedly of higher grade. From a point 6.1 m (20') west of the main crosscut on 3 level to a

point 24.4 m (80') east of main crosscut in the east drift, samples were taken over 0.3 m (1') of vein at 1.5 m (5') intervals. Over this 30.5 m (100') average grade is indicated to be 0.227 oz Au/ton. Footwall samples over 0.3 m (1') at the east end of this area returned an average of 0.026 oz Au/ton.

Similarly, from a point in the west drift 39.6 m (130') west of the crosscut to a point 59.5 m (195') in the west drift samples taken over 0.3 m (1') of vein gave an average grade of 0.216 oz Au/ton over a distance of 19.8 m (65'). Footwall samples over 0.3 m (1') averaged 0.028 oz Au/ton and one hangingwall sample over 0.3 m (1') reported 0.045 oz Au/ton.

Since old mine records and the presence of chutes indicate mining has taken place above this level, this informaiton may have implications for potential ore tonnage that apparently exists below this level.

DISCUSSION OF ALTERNATIVES TO EVALUATE THE KNOWN MINERALIZED SHOOTS

Vancouver Vein

The first priority remains to develop ore reserves in the Vancouver vein. To accomplish this, the access road to the Lower Vancouver portal should be completed. This will require at least 244 m (800') of road construction through about 5 areas (5 m? long each) of intermittent outcrops requiring drilling, blasting and dozing to establish a 2.5 m (8') wide road. If possible, this road should be continued to a drill site on the hangingwall (to the southeast of the portal). Two approaches to establish ore reserves may be considered:

a) Diamond drill from a point as close to the target area as possible. Although the preferable drill site would be on the hangingwall or southeast of the Lower Vancouver adit, it is possible that road construction costs would be prohibitive to reach that point. Depending on the drill site, about 366 m (1200') of drilling would be required to test the vein for continuity below the bottom of the underhand stope to elevation 1199.7 m (3935').

A site on the completed road could be selected northwest of the Lower Vancouver portal, thus drilling in the footwall and chasing the vein as it dips away from the drill location. Because of the angles of intersection, true widths of vein may not be understood so that ore may be indicated/inferred but not proven by this exercise. Discussions with experienced local drillers indicate that a Longyear Super 38 drill should be able to core at a rate of 40'/day at a cost of about $30/foot.

b) Sink a 1.5 m x 2.1 m (5' x 7') exploration/development shaft on the vein in the centre of the largest (eastern) underhand stope. This would require the installation of 42.7 m (140') of rail in the adit and ore bin/dumping facilities for 4x4 truck haulage at the portal. Some 250 tons of slashing for hoisting plant, sheave wheel and skip dump at the winze (shaft) collar would also be required. The determination of ore reserves could be proven by shaft sampling and mapping and possible sublevel sampling and mapping over 39.6 m (130') of shaft to elevation 1199.7 m (3935'). Overall costs for this work are estimated to be of the order of $800/foot for 130 feet of 5x7 shaft (includes ancillary work, slashing, etc.). Ore mined in this exercise would offset costs and this raise could be used as a supply/ventilation raise for mining or ore tonnage thus proven. To extract tonnage, a crosscut or drift would be required at elevation 1185 m (3885') or thereabouts to intersect the bottom of the shaft.

Cominco at Trail will readily purchase 300 to 400 tons of +95% siliceous gold ore containing about 0.5 oz/ton Au to yield $200-$225U.S./ton (Au currently $430.00U.S. per ounce). About three tons of rock would be mined per vertical foot in a 1.5 m x 2.1 m shaft. This approach requires more initial capital outlay than diamond drilling followed by drifting and raising.

Planning should proceed on the basis that Cominco will purchase +95% siliceous gold ore on a negotiated schedule based on detailed analysis of a representative bulk sample (raise or shaft). If an ore shoot is proven to have dimensions of 24.4 m x 0.92 m x 56.4 m (80' x 3' x 185') then a target of 3500-4000 tons is not unrealistic. Development work should then concentrate on a lower access road to elevation 1185 m (3885'), haulage

drift of about 122 m (400'), plus 56.4 m (185') of raise for the earliest returns possible.

If warranted, additional exploration should be undertaken to test the vein below the 1185 m (3885') level by drilling or shaft sinking as discussed previously.

Kootenay Belle Veins

Underground sampling in the Kootenay Belle Mine workings and examination of old records have revealed targets for exploration. Underground diamond drilling should test the "B" vein above and below 3 level to the east of the main crosscut. The Black vein should be investigated immediately below 3 level and below 7 level by diamond drilling from underground.

The Queen vein fracture has been explored only in short drifts on 2 and 3 levels. The 2 level may have penetrated the Upper Nugget quartzites on the Queen vein in only 6 m (20') of drift at the extreme northwest end of the workings, and did not explore the horizon in the Lower Nugget quartzites at all. On 3 level the Queen horizon was tested only in the unfavourable argillaceous quartzites of the Middle Nugget. If accessible, the 2 level exposure of the Queen should be sampled. Consideration should be given to additional exploration along the Queen structure.

Hideaway Adit

The advancement of the Hideaway adit should be considered on the basis of increased penetration of favourable quartzites to the east into the Midnight Fraction claim. This extension of the drift would improve the positioning of drill stations from which the Black, "B", and Vancouver veins could be probed. When longitudinal sections of the productive ore shoots in the main Kootenay Belle workings are overlain, the trend southerly from one vein to the next shows an alignment that falls on the Hideaway structure in the Midnight claim, approximately 137-168 m (450-550') ahead of the present face. Mineralization is anticipated to occur in this location.

OTHER EXPLORATION TARGETS

1. The 5 claims which were recently acquired contain at least two formerly productive veins (Yellowstone, Dixie) and the eastern extension of one productive horizon (Queen). The Yellowstone vein has been sampled in the lowest adit; results have not yet been received but will be the subject of a subsequent report. The Dixie adit should be re-opened and the workings sampled.

A soil geochemical survey should be extended onto the 5 new claims from the Kootenay Belle grid which was established in 1980-81.

2. Anomalies which were located in the earlier soil geochemical survey should be prospected in detail by close-spaced soil sampling and hand trenching. Old pits shown on the extension of the Yellowstone and "A" veins within the Yosemite and Rio Tinto claims should be found, cleaned, and sampled. A survey plan of Kootenay Belle Gold Mines dated Sept. 5, 1937 shows two proposed surface drill holes spotted to test the Yellowstone structure in the northwest corner of the Rio Tinto claim. This location would be in the favourable quartzites. Presumably there was enough encouragement from mineralization in the pits to consider a drill test. No records have been found to indicate that the drilling was ever undertaken. Anomalous gold and lead in soils were obtained in this area.

3. The concept has been presented (Goldsmith, November, 1982) that faulted segments of known vein structures as well as unknown vein structures in favourable quartzites may exist below overburden-covered areas in the Wolf and Sheep Creek valleys. Drilling of overburden by percussion equipment would define the bedrock profile in preparation for diamond drilling if cover is not prohibitively thick. Initially one fence of diamond drill holes is proposed from south to north to prospect for gold-bearing veins.

4. The high gold values from the adit at 2+10NW of the Lower Vancouver adit occur in a vein fracture which is hosted in unfavourable argillaceous quartzites. No expression of this fracture has been observed to the east, where it should pass through clean quartzites, because of soil cover. An

anomalous soil sample at 9+00S, 1+00E containing 320 ppb Au may be derived from this structure. Prospecting and trenching is required.

The mineralization in the 2+10NW adit lies on the projected up-dip extension of the vein fracture exposed in the Hideaway adit where high gold values have been obtained from several locations. The intervening dip length is a target worthy of exploration.

CONCLUSIONS

Exploration to date has partially evaluated four gold-bearing shoots on three vein fractures. Indications of one or two additional shoots in the Hideaway adit have also been observed. The recently-acquired Yellowstone and Dixie veins have yet to be appraised although sampling has been completed in a section of the Yellowstone workings. Unmined sections and depth extensions below 6 level in the Kootenay Belle main workings remain untested.

Potential exists for locating new gold deposits on eastern extensions of the Vancouver, Hideaway, Yellowstone and Queen horizons. Exploration to the west and northwest below the valleys of Wolf and Sheep creeks could locate near-surface extensions of the Yellowstone and Dixie veins and possibly discover unknown structures in an untested area beneath Sheep Creek.

If high-grade tonnage can be developed in the shoot below the Lower Vancouver adit, it could possibly be blended with material mined from other veins on the property to upgrade a larger tonnage for delivery to Cominco or elsewhere. The value of the silica in the Kootenay Belle ores can be expected to pay for smelter charges, leaving the precious metal content to cover mining and transportation costs, and to provide an operating profit.

A vigorous exploration programme is recommended to assess the known mineralized zones and to search for new shoots on fault structures which are mineralized at various places along their length and depth.

RECOMMENDATIONS

As a first Phase, the six recently acquired reverted Crown grants should be prospected and covered by a geochemical soil/rock chip survey. Detailed prospecting should be completed on the original claims in the vicinity of vein fractures or soil geochemical anomalies. The Dixie adit has been located and should be re-opened for evaluation.

The second Phase should entail construction of a drill access road, preferably to a site on the hangingwall of the Vancouver vein, i.e. to the southeast of the Lower Vancouver portal. A drill contract for approximately 366 m (1200') of BQ surface diamond drilling in 4-5 holes using a Longyear Super 38 or equivalent drill should be let. Adequate surface/underground/borehole survey control in the vicinity of the Vancouver workings is required for correct orientation and interpretation of data.

With sufficient encouragement from drilling, the next Phase is to prepare a complete feasibility study to determine the economics of mining the tonnage and grade indicated. In addition to considering sale or ore to Cominco, the local David Minerals custom mill may be available and its use should be investigated. This third Phase would entail base map (1:500) production from air photographs, surface-underground survey control, comprehensive geological mapping, and further statistical analysis of geochemical trace elements to provide a data base from which predictability of the location of ore shoots may be possible.

On the recommendations of a feasibility study, mining of 3000-4000 tons of ore above the 1185 m (3885') elevation as a fourth Phase should proceed.

Phase five would comprise additional exploration in the Vancouver vein and other veins that may be considered to exist in the Sheep Creek valley.

Phase six is recommended to test possible targets in the vicinity of the Kootenay Belle workings by drifting easterly in the Hideaway adit and by underground diamond drilling. Dewatering of the lower Kootenay Belle levels should be considered at this time.

Phases 3-6 could be undertaken in a different sequence subsequent to the completion of Phase 2 and to the recommendations derived therefrom.

COST ESTIMATES

Phase 1

Geochem, prospecting, reporting	$15,000	
Open Dixie adit	5,000	
	$20,000	
Contingencies @ 10%	2,000	
Total, Phase 1	$22,000	$ 22,000

Phase 2

Access road to Vancouver vein hangingwall	$ 8,000	
Provision of water for drilling	2,000	
Diamond drilling, 366 m @ $115/m (1200' @ $35/ft)	42,000	
Supervision, engineering	10,000	
Room, board, vehicle, supplies	4,000	
Analyses	1,000

Contingencies @ 20%	215,000	
Total, Phase 6	$1,290,000	$1,290,000
TOTAL, SIX PHASES		$2,034,000

Beginning with Phase 2, each Phase should be documented in an engineering report; undertaking of the subsequent Phase should be contingent upon receiving favourable recommendations from an engineer.

Respectfully submitted,

PAUL KALLOCK

Paul Kallock
Consulting Geologist

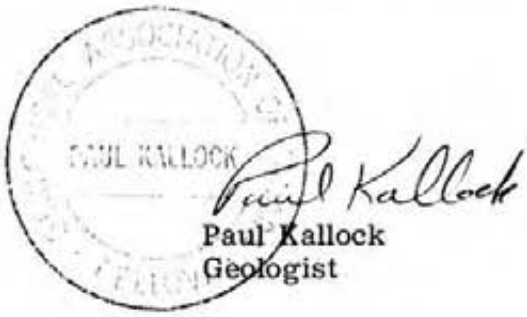
GEOLOGIST'S CERTIFICATE

I, Paul Kallock, state that:

1. I have a B.Sc. degree in Geology from Washington State University, 1970. I am a Fellow of the Geological Association of Canada.
2. I have engaged in mineral exploration since 1970, both for major mining and exploration companies and as an independent geologist.
3. I have co-authored the report entitled, "Underground Diamond Drilling, Geological Mapping, and Sampling, Kootenay Belle Property, Sheep Creek Camp, Nelson Mining Division, Salmo, B.C." The report is based on my fieldwork carried out on the property and from previously accumulated geologic data.
4. I have no direct or indirect interest in any manner in either the property or securities of Amore Resources Inc., or its affiliates, nor do I anticipate to receive any such interest.
5. I consent to the use of this report in a prospectus or in a statement of material facts related to the raising of funds.



Paul Kallock
Geologist

Vancouver, B. C.
July 28, 1983

ENGINEER'S CERTIFICATE

NORMAN C. DAVIDSON

1. I, Norman C. Davidson, am a Registered Professional Engineer in the Provinces of British Columbia, Nova Scotia and Ontario. My address is P.O. Box 39, St. Andrews, Antigonish County, Nova Scotia B0H 1X0.
2. I am a graduate of Michigan Technological University, Houghton, Michigan, U.S.A. with a B.Sc. in Mining Engineering. I am a graduate of the Haileybury School of Mines as a Certified Mining Technician. I am registered as a Mine Manager under the Coal Mines Regulation Act of Nova Scotia. I am a member of C.I.M., A.I.M.E., and the Mining Society of Nova Scotia.
3. I have been engaged in mining exploration, development and mine production for 21 years.
4. I have co-authored the "Report on the Kootenay Belle Property, Sheep Creek Camp, Nelson Mining Division, Salmo, B. C." The report is based on field work performed and supervised by the author.
5. I have no interest either directly or indirectly in the claims named herein or Amore Resources Inc., nor do I expect to receive any.
6. I consent to the use of this report in a prospectus or in a statement of material facts related to the raising of funds.

Sample Identification | File #24769

Sample 1: LV-V 1 + 40-8 (2.527 oz. Au)

Sample 2: LV-V 1 + 50 (.201 ")

Sample 3: KB 3B 2 + 15E (.260 ")

Sample 4:

Sample 5:

Percentages of the various elements expressed in these analyses may be considered accurate to within plus or minus 35 to 50% of the amount present.

Semi-quantitative spectrographic analytical results for gold and silver are normally not of a sufficient degree of precision to enable calculation of the true value of ores. Therefore, should exact values be required, it is recommended that these elements be assayed by the conventional Fire Assay Method. Quantitative and Fire Assays may be carried out on the retained pulp samples.

Silicon, aluminum, magnesium, calcium and iron are normal components of complex silicates.

MATRIX – Major constituent
MAJOR – Above normal spectrographic range
TRACE – Detected but minor amounts
N.D. – Not detected
• – Suggest assay (above 0.3%

All results expressed as PERCENT

Note Pulps retained one week

120.0	End of hole.									
	87.4% core recovery.									

GEOCHEMICAL PROVENANCE IN DRILL HOLES

GEOCHEMICAL PROVENANCE IN DRILL HOLES

The first diamond drill hole, KB-83-1, encountered a 0.002 m (1/16")-thick sphalerite veinlet at 30.8 m (101.1') of depth. It contained lesser pyrite and galena, weak quartz and traces of clay. A 0.05 m (2") sample across the vein yielded 0.348 oz Au/ton, 138 ppm Cu, 970 ppm Pb, 19 ppm Mo, 0.1 oz Ag/ton and 16 ppm As. Samples taken 0.3 m (1') on each side of this veinlet show lead elevated by 2 to 3 times background, and molybdenum by 3 to 6 times background. Copper and arsenic show no enrichment.

Other areas of anomalous gold (greater than 100 ppb) are:

14.0-14.3 m (46.0-47.0') which contains 640 ppb Au, 3.9 ppm Ag, and 14 ppm Pb;

204-209' contains 780 ppb Au;

269-274' contains 125 ppb Au, 20 ppm Cu, 13 ppm Pb and 7 ppm As;

304-309' contains 130 ppb Au and 15 ppm Pb;

428-433' contains 270 ppb Au.

One area of note which did not contain appreciable gold is 274-279' which contains 6.3 ppm Ag, 30 ppm Pb and 16 ppm Cu.

The second diamond drill hole, KB-83-2, only intersected a few areas of note:

Interval (feet)	
20-25	400 ppm Cu
32.5-33.4	22 ppm Mo, 45 ppm Pb
64-65	18 ppm Mo, 14 ppm Pb
68-68.7	0.32 oz/ton Ag
78-83	125 ppb Au

A listing of samples of note in the third diamond drill hole, KB-83-3, is as follows:

Interval (feet)	Au	Ag	Mo (ppm)	Pb (ppm)	Cu (ppm)	As (ppm)
82.5-85.0	100 ppb					
90.0-92.5	0.006 oz		16			4
95.0-97.5	0.010 oz	0.12 oz	8			
100.0-102.5	0.010 oz		13			
102.5-105.0	0.018 oz	0.06 oz	13			
148-151	210 ppb					
228-233	295 ppb					
247-252	280 ppb				12	
252-256	275 ppb					
256-258	0.010 oz	0.16 oz	15	51		
283-284	0.008 oz	0.18 oz	10	20		8
284-287	145 ppb					5
287-290	165 ppb					
290-294	220 ppb					

Other intervals without appreciable gold but anomalous in other elements in KB-83-3 are:

Interval (feet)	Ag	Mo (ppm)	Pb (ppm)
85.0-87.5		14	18
87.5-90.0	0.08 oz	14	14
92.5-95.0		7	
98.3-98.6	0.08 oz	22	12
105-107.5	0.06 oz	9	
107.5-110.0		9	
294-297	2.1 ppm		

Diamond drill hole #4, KB-83-4, contains several zones of significant gold as follows:

Interval (feet)	Au	Ag (ppm)	Pb (ppm)	As (ppm)
31-36	300 ppb			
36-41	350 ppb			
174-179	265 ppb			
194.2-194.7	0.032 oz	3.9	39	
196.9-197.15	0.046 oz	4.1	16	11
197.15-198.0	140 ppb	2.5	26	20
199.2-199.5	0.050 oz	2.3	46	28

Only one zone in KB-83-4 is distinct in base metals without coincident gold.

191.1-191.33 has 18 ppm Cu, 133 ppm Pb, 2.2 oz Ag/ton, 10 ppm Mo, and 265 ppm As.

A large zone between 187.5 and 211.0 is anomalous in Ag and Pb, however analytical error may account for its distinctly elevated values.

Four samples from KB-83-4 were analysed spectrographically for 34 elements each. No distinctly anomalous elements were found except weak but noteworthy barium to 0.05%, chromium to 0.08%, and cobalt to 0.03%. These elements appear to be slightly higher than expected for the geological environment of the Sheep Creek camp.

Diamond drill hole KB-83-5 contains two weak but anomalous areas of gold mineralization:

Interval (feet)	Au (ppb)	Cu (ppm)	Pb (ppm)	Mo (ppm)	Ag (ppm)	As (ppm)
131-136	355					
136-139		69	20			14
139-144					7.3	
214.7-215.0	130	520	29	14	6.1	17

Within the interval from 131'-144', base metals are anomalous outside the gold-bearing zone. In the 214.7'-215.0' interval, a quartz vein with 30% pyrrhotite and less than 0.5% chalcopyrite is present.

Diamond drill hole KB83-6 encountered a vein zone at 166.5':

Interval (feet)	Au	Pb (ppm)	Ag
106.0-106.25	170 ppb	25	
106.25-106.75	0.087 oz	97	1.5 ppm
106.75-107.0		19	

Two parallel veinlets at 106.5' crosscut bedding at 50° to core axis. Host is light brown to pale green quartzite. Each veinlet has pyrite, chlorite and clay. Traces of galena are apparent in one of the fractures. Displacement on opposite sides of veinlets appears to be minor.

LIMESTONE EXPOSED IN ROAD CUT 155 ft. (47.24 m) WEST OF PORTAL
LAMPROPHYRE DIKE
ZONE OF SILICIFICATION WITH 5-15% DISSEMINATED MAGNETITE
LOCALLY SCHISTOSE ARGILLITE
DARK CHLORITE SCHIST WITH LESSER ARGILLITE
SCHIST AND ARGILLITE WITH NUMEROUS QUARTZ LENSES PARALLEL TO FOLIATION OR BEDDING
GREY TO TAN IRON STAINED QUARTZITE WITH NUMEROUS INTERBEDS OF DARK GREY QUARTZITE AND ARGILLITE
JOINT SURFACE WITH PYRITE COATINGS
GENERALLY ±50% DARK ARGILLACEOUS QUARTZITE AND ARGILLITE
WEAK DEFORMATION AND FRACTURING OF DIKE AT LEAD INTERSECTION
MOSTLY GREY BROWN QUARTZITE INTERBEDDED WITH ≤ 25% DARK ARGILLACEOUS QUARTZITE
HANGING WALL SPLIT
2m RIGHT LATERAL MOVEMENT ON MAIN LEAD
IRREGULAR QUARTZ PODS AND LENSES
1m QUARTZ VEIN PARALLEL TO CONTACT OF FELDSPAR-QUARTZ PORPHYRY DIKE; LOCAL BLEBS OF CHLORITE-PYRRHOTITE-PYRITE
2.5-15 cm WITH 1-3% PYRRHOTITE
ZONE OF STRONG DEFORMATION OF ARGILLITE AND ARGILLACEOUS QUARTZITE. MOST FOLDING APPEARS TO BE FAULTED IN CRESTS OR TROUGHS.
SHEAR ZONE: INTENSELY FRACTURED, ABUNDANT CLAY.
NUMEROUS IRREGULAR QUARTZ LENSES TR. PYRITE, LOCAL CHLORITE
DARK GREEN CHLORITIC ARGILLITE
SEVERAL STACKED HORIZONTAL SHEAR ZONES BETWEEN STEEPLY-DIPPING FAULTS.
STOPE AREA (0-80-1-50) SHOWN IN LONGITUDINAL SECTION
DISTINCT HANGINGWALL. GRADATIONAL ACROSS FOOTWALL WITH PYRITE MINERALISED IN QUARTZITE
TIGHT FRACTURE FOLLOWS N. SIDE OF BACK
DRIFT FOLLOWS FW 5.0' FROM PORTAL, WIDENS
QUARTZITE, WHITE, GREY TO BLACK, ALTERNATING REGULARLY WITH ARGILLACEOUS QUARTZITES; MODERATELY SHEARED.
STRONG FRACTURES
BROWN ARGILLITE - QUARTZITE BROKEN ALONG BEDDING
6' DARK QUARTZITE WITH INTERBEDDED ARGILLITE
6' DARK ARGILLITE
SILICEOUS FW w/ CLAY-SERICITE FR TO 5% LOCAL PYRITE IN BLEBS AND VEINLETS
UNDERHAND STOPES
MASSIVE QUARTZ IN BEDDING PLANE
WHITE-GREY MASSIVE QUARTZITE
LT. GREY QUARTZITE WITH DARK ARGILLITE PARTINGS EVERY 2"-4"
FRACTURED PYRITE. MINERALIZED QUARTZ VENEERS ON QUARTZITES.
TR MALACHITE IN BACK.
HOST ROCK IS ARGILLITE AND ARGILLACEOUS QUARTZITE
10% PYRITE IN MASSIVE QUARTZ VEIN MATERIAL
OXIDIZED AND LEACHED
LOCALIZED SHEARING
MASSIVE WHITE AND GREY QUARTZITE
MASSIVE LT. GREY TO LT. BROWN QUARTZITE
LIGHT GREY TO WHITE GENERALLY MASSIVE QUARTZITE WITH OCCASIONAL 0.6-1.2 cm SERICITE SCHIST INTERBED.
±1% DISSEMINATED GALENA AND SPHALERITE
IRREGULAR CALCITE VEINS
QUARTZ VEIN FOLLOWS LEAD FOR 1 m
ARGILLITE AND ARGILLACEOUS QUARTZITE BANDING IN WHITE TO GREY QUARTZITE
BRECCIA ZONE: SUB-ANGULAR TO ROUNDED CLASTS OF QUARTZITE AND SCHIST UP TO 12". STRONG ARGILLIC TO MODERATE SILICEOUS ALTERATION. MAIN LEAD IN DRIFT MAY BE SLIGHTLY OFFSET IN BRECCIA.
1"-2" QUARTZ-MAGNETITE VEIN AT NORTHEAST CONTACT.
PERVASIVE, STRONG LIMONITE STAIN LOCAL HEMATITE.
NO SULPHIDES OR BOXWORK STRUCTURES.
ZONE IS PRODUCING WATER.
MANGANESE OXIDE COMMON
1.5 m x 3.6 m RAISE 33.8 m TIMBERED
INTERBEDS OF CHLORITE SCHIST SHOWING VERTICAL SLICKENSIDES.
7.5-9 m RAISE
QUARTZ LENSES SUB-PARALLEL TO BEDDING
3.5-4.5 m RAISE
3-4% FRACTURE-FILL PYRITE
POOR FOOTWALL EXPOSURE
