SUMMARY

This assessment report presents the results of a soil geochemical survey on the Troitsa Peak Property (Orange claim group) conducted during the period 18 June to 9 August 1983. The property is located in the Whitesail Range 135 km south of Smithers in central British Columbia.

The area studied is underlain mainly by a sequence of andesitic flows and tuffs of the Jurassic age Hazelton Group. These strata are cut by irregular plugs of diorite and by quartz feldspar porphyry dykes. Quartz veins occur locally in the andesitic flows and tuffs.

Some 1332 soil samples were collected at 25 m intervals on grid lines 100 m apart, and analysed geochemically for Au, Ag, Pb, Zn, Cu and Mo. The data yielded 11 distinct anomalies, two of which are associated with known mineralized quartz veins. Prospecting has located mineralized quartz vein float associated with three other of the anomalies and further prospecting is required to locate the source of this float. Seven additional anomalous zones remain to be investigated to determine their source.

INTRODUCTION

General Statement

This report presents results of a soil geochemical survey on the Cummins North, Cummins South, Wind Tunnel and Jesse claims of the Troitsa Peak Property, conducted over the period 18 June to 9 August, 1983. A total of 1332 soil samples were collected over a 32.3 line km flagged grid (Cummins Creek Grid). Base map control was provided by a 1:2,000 scale topographic base map enlarged from a 1:10,000 scale base map, with a 20 m contour interval, prepared by Pacific Surveys of Vancouver from existing air photographs.

Soil sampling and grid preparation was conducted by five field assistants under the direction of B. Goad and N. Cawthorn.

Location, Access, Topography

The Troitsa Peak property is located in the Whitesail Range, between Whitesail Lake to the south and Tahtsa Reach to the north, in central British Columbia (Fig. 1). The property is some 135 km south of Smithers.

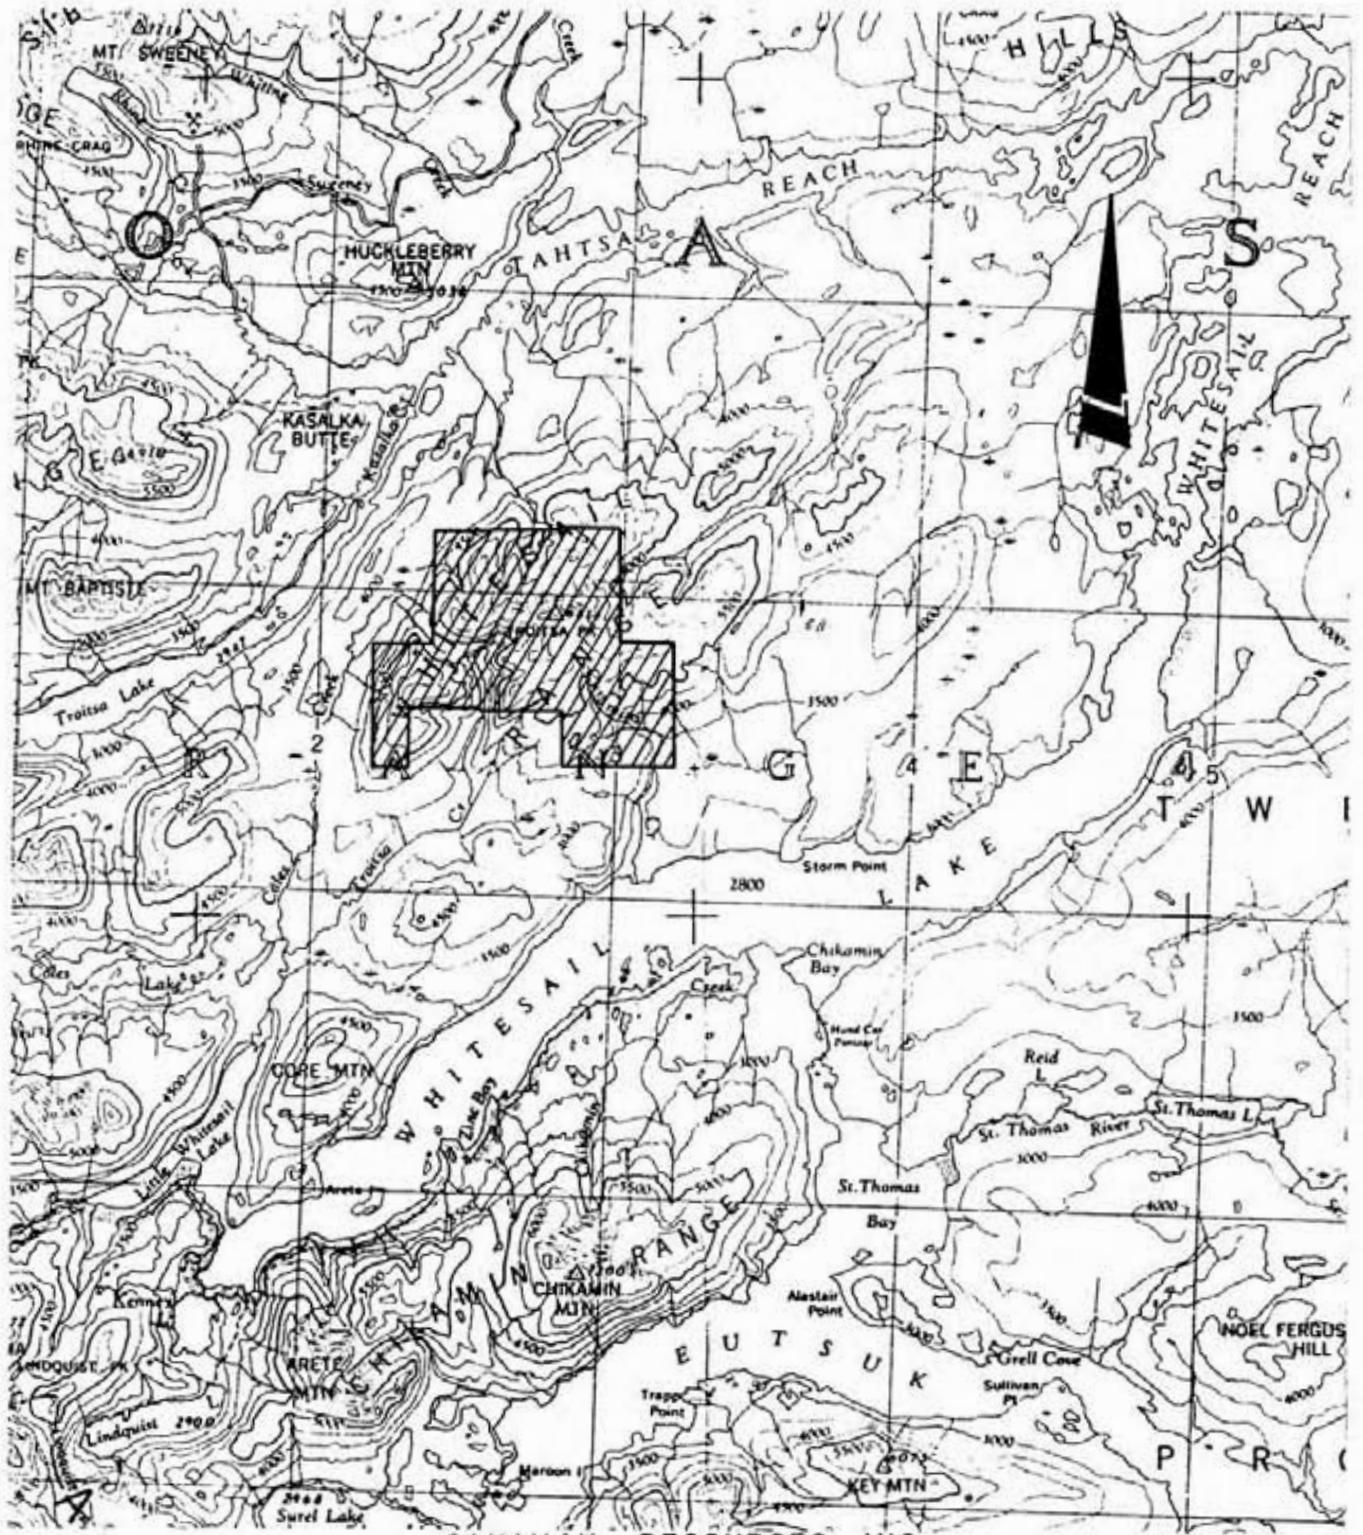

Access is by helicopter from Smithers or Houston, B.C.

The claims are centred around Troitsa Peak (2089 m). Elevations within the area of work described in this report range from 1020 m in the southeast to a maximum of 1620 m in the northwest. Almost all of this area is below tree line.

Claims Data

The Troitsa Peak Property consists of 15 contiguous claims totalling 252 units (Fig. 2). The claims were staked over the period 1981-83 and all are currently held in the name of Canamax Resources Inc. All are located within the Omineca Mining Division.

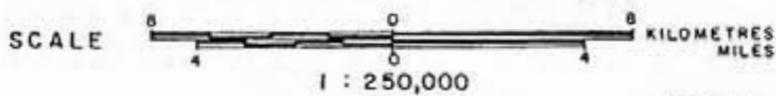

The work described in this report is being applied as two years' assessment in each of the following claims: Cummins North, Cummins South, Wind Tunnel and Jesse. The claims will be grouped as of the assessment filing date into three groups as tabulated below.

Property History

A group of six claims were staked on behalf of Union Carbide Canada Ltd. in late 1981. Union Carbide subsequently staked an additional five claims during 1982. The title was transferred to Canamax Resources Inc. in early 1983 and Canamax staked a further four claims.

During the 1982 field season Union Carbide carried out mapping at a scale of 1:10,000, and preliminary rock, stream sediment and soil geochemical sampling on nine of the then existing claims. This work is detailed in an assessment report -- "Geological and Geochemical Survey of the Troitsa Peak (North) and Troitsa Peak (South) Claim Groups, Omineca Mining Division, British Columbia" by N.G. Cawthorn, submitted in December, 1982.

There is no record of any previous work on the claims area, although a few old exploration pits were encountered during the course of detailed exploration in the area described in this report.

Local Geology

The Cummins Creek area investigated in this assessment report is underlain predominantly by green andesitic flows and lapilli tuffs of Lower Jurassic age. Locally these are intruded by younger feldspar porphyritic diorite dykes and plugs. In the northern part of the grid area the volcanics are cut by several quartz feldspar porphyry dykes. Quartz veins up to 1.5 m wide and 150 m long, and with variable trends from northwest to northeast, occur within the volcanics.

GEOCHEMISTRY

General Statement

A total of 1332 soil samples were collected at 25 m intervals on 29 parallel southwesterly trending lines 100 m apart. The lines are up to 1.4 km in length for a total of 32.3 line km. Soils were collected using a mattock from a depth of 20 cm and samples were collected from "B" horizon soils.

All the samples were submitted to Rossbacher Laboratory, Burnaby, B.C. and analysed geochemically for Au, Ag, Pb, Zn, Cu and Mo. Analytical procedures and results are detailed in Appendix III. Sample locations with results for Au and Ag are shown in Figures 3a and 3b; and with results for Pb, Zn, Cu and Mo in Figures 4a and 4b.

Results and Interpretation

Rigorous statistical methods have not been used to evaluate the results. However, data from another geochemical grid on the property (the "Moraine" grid) and described in a previous assessment report (see "1983 Geochemical and Geological Surveys, Assessment Report, Troitsa Peak Property" by N.G. Cawthorn, dated 16 November 1983) indicated that the anomalous and highly anomalous thresholds tabulated below are appropriate for the property as a whole (the Peak Values listed are from the "Cummins Creek" Grid).

	Anomalous Threshold	Highly Anomalous	Peak Value
Au	20 ppb	100 +	200
Ag	0.8 ppm	2.0 +	7.4
Pb	100 ppm	500 +	1,420
Zn	200 ppm	500 +	660
Cu	100 ppm	200 +	1,000
Mo	5 ppm	10 +	58

To enable direct comparison between the two grids the same anomalous thresholds have been applied in interpretation of the Cummins Creek Grid. It should be noted however that there are some differences in the geochemical response between soils of the two grids. In particular, lead values are much lower in soils on the Cummins Creek Grid, where only two samples contained more than the anomalous threshold of 100 ppm Pb. For the Cummins

Creek Grid, soil samples containing over 25 ppm Pb can be considered to have elevated lead contents.

Examination of the data reveals that many of the anomalous samples for all elements occur as low-order singleton, or at most two sample, anomalies. These are thought to be of little economic significance and have been disregarded in interpretation of the data unless the analytical values are highly anomalous. Contouring of the data for individual elements is found to be of little assistance in interpretation. Rather, anomalous zones have been defined within which many, if not all, of a group of samples are seen to be anomalous in one, or several, elements. These anomalous zones are identified by letter on the geochemical maps and are described below:

Anomaly A is located close to Cummins Creek between lines 20+00N and 25+00N. Most samples are anomalous in silver (up to 3.0 ppm Ag) and several of the samples are also anomalous in gold, copper, molybdenum and one sample is anomalous in lead. This zone is closely associated with two quartz veins up to 1.5 m wide and 150 m long. Locally the quartz veins contain pyrite, galena, sphalerite, chalcopyrite and argentite giving rise to the anomalous values. The anomalous zone indicates little extension of these veins beyond their exposed extent, although a group of samples on line 20+00N at 3+00 to 3+50W may indicate some south-southeasterly extension of a vein exposed in Cummins Creek at 21+50N.

Anomaly B is a group of samples most of which are highly anomalous in copper - up to 720 ppm Cu - but are not anomalous in any other element. This appears to be related to an area of outcrop of dark green andesite and probably represents a somewhat elevated copper content of the andesite. No copper mineralization has been observed in the locality.

Anomaly C is a group of four samples on line 25+00N at 4+50 to 5+50E which are anomalous in silver (maximum 1.4 ppm Ag) but not in other elements. This is probably related to narrow (5-10 cm wide) quartz veins observed in andesite at this locality.

Anomaly D is a single sample anomaly on line 20+00N at 2+25E. The sample at this locality (WSS252) contained 200 ppb Au - the highest value obtained from this grid - but was not anomalous in other elements. This site was resampled (WNS704) but the anomalous gold content was not confirmed -

the sample contained only 10 ppb Au. The resample, however, was extremely anomalous in lead (1420 ppm Pb) as well as silver (6.0 ppm Ag) and copper (150 ppm Cu). A group of closely spaced (5-10 m) soil samples in the vicinity were not anomalous, and neither was a rock chip from nearby andesite outcrop. A northerly-trending shear zone with associated quartz veinlets is exposed along a creek 150 to 300 m due north of this sample locality, grab samples of which are anomalous in gold and silver. Anomaly D probably represents similar spotty mineralization on an extension of this fault.

Anomaly E is a group of samples on lines 17+00N and 18+00N between 1+25E and 3+50E which are typically anomalous in silver (up to 1.6 ppm Ag) but not in other elements. This locality has not been investigated in detail and the source of the anomaly is not known. A quartz porphyry dyke is exposed in the creek immediately west of here, and a grab sample of the dyke was slightly anomalous in silver. The anomaly may represent an extension of the quartz porphyry dyke.

Anomaly F is a group of samples at the extreme western end of lines 20+00N and 19+00N which are anomalous in silver (up to 3.0 ppm Ag) and locally anomalous in molybdenum. Prospecting in this area located several float blocks, up to 45 cm in size, of vein quartz which are anomalous in silver, lead and molybdenum (but not gold).

Anomaly G is a group of scattered samples in the western parts of lines 17+00N and 16+00N which are anomalous in silver (up to 1.8 ppm Ag) and gold (up to 90 ppb Au). This locality has been partially prospected and several float blocks, up to 50 cm in size, of vein quartz were found which contain patches of pyrite, chalcopyrite, galena, sphalerite and argentite. Selected grab samples of this material are highly anomalous in gold, silver and base metals. A pair of samples on line 17+00N at 3+75 and 4+00W are anomalous in gold (70 ppb and 90 ppb Au). This part of the anomalous zone has not been prospected. As the mineralized quartz float was found 100 to 150 m east and downslope of these samples, the area should be further prospected.

Anomaly H is a group of three samples on line 15+00N at Cummins Creek which are highly anomalous in copper, anomalous in zinc, and contain elevated lead contents. The samples are not anomalous in precious metals.

A float block of quartz containing patchy galena, sphalerite, chalcopyrite, and argentite has been found in Cummins Creek at this locality. Selected grab samples of this float boulder have yielded assays of up to 1.34 oz/ton Au and 293 oz/ton Ag (1982 sample PS129R). In view of the presence of this float the anomalous locality should be further prospected.

Anomaly I is a 500 m long zone extending from the western end of line 14+00N to line 11+00N at 1+50E. The central part of the zone is anomalous in silver (up to 1.8 ppm Ag) associated with a broader area highly anomalous in copper (up to 1,000 ppm Cu) and molybdenum (up to 37 ppm Mo). Several samples on line 14+00N are anomalous in gold (up to 100 ppb Au) and a couple of samples on line 12+00N are anomalous in zinc (up to 660 ppm Zn). Several samples also have elevated lead contents. This extensive multi-element anomaly is closely associated with, and clearly related to, an east-northeasterly trending feldspar quartz porphyry dyke. Disseminated pyrite and minor chalcopyrite occur in the dyke, and trace amounts of sphalerite have been seen in quartz veinlets in the dyke. Up to 3% pyrite is developed in andesite adjacent to the dyke. The gold values appear to be associated with the pyrite. Although the anomaly is extensive (and open to the west) and the dyke can be traced for over a kilometre the associated precious metal mineralization is not believed to have any economic potential.

Anomaly J is a group of samples on lines 8+00N and 7+00N from 2+25E to 3+50E which are anomalous in silver (up to 1.6 ppm Ag) but not in other elements. The area is underlain by andesite but the anomalous locality has not yet been prospected and the source of the anomaly is not known.

Anomaly K is a single sample anomaly on line 3+00N at 1+75E. This singleton anomaly is significant in that it is the highest silver value (7.4 ppm Ag) recorded for this grid. The source of this anomaly is not known and the locality should be prospected and resampled.

Discussion

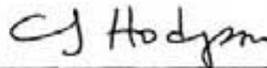

The soil geochemical data have served to delineate a number of areas with anomalous Ag, Au, Pb, Zn, Cu and Mo. Several of the anomalies, in particular anomalies A and I, are associated with known showings. Prospecting has revealed the presence of anomalous quartz float associated with

several of the anomalous zones, in particular anomalies F, G and H, and further prospecting and sampling of these areas should be carried out to locate the source of the float. Several of the lesser anomalies (anomalies E, J and K) have not been investigated and should be resampled and prospected to confirm and determine their source.

N. G. Cawthorn

GEOCHEMICAL ANALYTICAL METHODS CURRENTLY IN USE AT ROSSBACHER LABORATORY LTD.

A. SAMPLE PREPARATION

1. *Geochem. Soil and Silt:* Samples are dried, and sifted to minus 80 Mesh, through stainless steel, or nylon screens.
2. *Geochem. Rock:* Samples are dried, crushed to minus $\frac{1}{2}$ inch, split, and pulverized to minus 100 mesh.

B. METHODS OF ANALYSIS

1. *Multi element:* (Mo, Cu, Ni, Co, Mn, Fe, Ag, Zn, Pb, Cd):
0.5 Gram sample is digested for four hours with a 15:85 mixture of Nitric-Perchloric acid.
The resulting extract is analyzed by Atomic Absorption spectroscopy, using Background Correction where appropriate.
2. *Antimony:*
0.50 Gram sample is fused with Ammonium Iodide and dissolved.
The resulting solution is extracted into TOPO/MIBK and analyzed by Atomic Absorption spectroscopy.
3. *Arsenic:*
0.25 Gram sample is digested with Nitric-Perchloric acid.
Arsenic from the solution is converted to arsine, which in turn reacts with silver D.D.C. The resulting solution is analyzed by colorimetry.
4. *Barium:*
0.50 Gram sample is repeatedly digested with HClO_4 , HNO_3 , and HF.
The solution is analyzed by Atomic Absorption spectroscopy.
5. *Biogeochemical:*
Samples are dried, and ashed at 550°C . and the resulting ash analyzed as in *1, multielement analysis.
6. *Bismuth:*
0.50 Gram sample is digested with Nitric acid. The solution is analyzed by Atomic Absorption spectroscopy.
7. *Chromium:*
0.25 Gram sample is fused with Sodium Peroxide. The solution is analyzed by Atomic Absorption spectroscopy.

Rossbacher Laboratory

GEOCHEMICAL ANALYSTS & ASSAYERS

2225 S. SPRINGER AVE.,
BURNABY, B. C.

TELEPHONE: 299-6910
AREA CODE: 604

(2)

METHOD OF ANALYSIS (CONT.)

8. *Fluorine:* 0.50 Gram sample is fused with a Carbonate Flux, and dissolved.
The resulting solution is analyzed for Fluorine by use of an Ion Selective Electrode.
9. *Gold:* 10.0 Gram sample is roasted at 550°C. and dissolved in Aqua Regia. The resulting solution is subjected to a Methylisobutyl Ketone extraction, which extract is analyzed for Gold using Atomic Absorption spectroscopy.
10. *Mercury:* 1.00 Gram sample is digested with Nitric and Sulfuric acids. The solution is analyzed by Atomic Absorption spectroscopy, using a cold vapor generation technique.
11. *Partial Extraction and Fe/Mn oxides:* 0.50 Gram sample is extracted using one of the following: Hot or cold 0.5 N. HCL, 2.5% E.D.T.A., Ammonium Citrate, or other selected organic acids. The solution is analyzed by use of Atomic Absorption spectroscopy.
12. *pH:* An aqueous suspension of soil, or silt is prepared, and its pH is measured by use of a pH meter.
13. *Rapid Silicate Analysis:* 0.10 Gram sample is fused with Lithium Metaborate, and dissolved in HNO₃.
The solution is analyzed by Atomic Absorption for SiO₂, Al₂O₃, Fe₂O₃, MgO, CaO, Na₂O, K₂O, TiO₂, P₂O₅, and MnO.
14. *Tin:* 0.50 Gram sample is sublimated by fusion with Ammonium Iodide, and dissolved.
The resulting solution is extracted into TOPO/MIBK and analyzed by Atomic Absorption spectroscopy.
15. *Tungsten:* 1.00 Gram sample is sintered with a carbonate flux, and dissolved.
The resulting extract is analyzed colorimetrically, after reduction with Stannous Chloride, by use of Potassium Thiocyanate.

NOTE -
Labeled anomalous zones referred to in the text

SYMBOLS

- Soil Sample site, sample number; >10ppb Au, >0.2 ppm Ag
- Silt
- Geochemical anomalous zone boundary (values >20ppb Au and/or >0.8 ppm Ag, >100 ppm Pb, >200 ppm Zn, >200 ppm Cu > 10 ppm Mo)
- Trench
- Grid line
- Claim boundary
- Claim unit boundary
- Stream
- Topographic contour (contour interval 20 metres)
