INTRODUCTION

This report summarizes exploration activities carried out on the OPEC 6-9 and HY 1-2 claims between June 13 and September 3, 1983. The OPEC claims are under option to Anaconda from Golden Rule Resources of Calgary, Alberta. The HY 1-2 claims were staked by Anaconda in 1983, and are included within the agreement.

LOCATION AND ACCESS

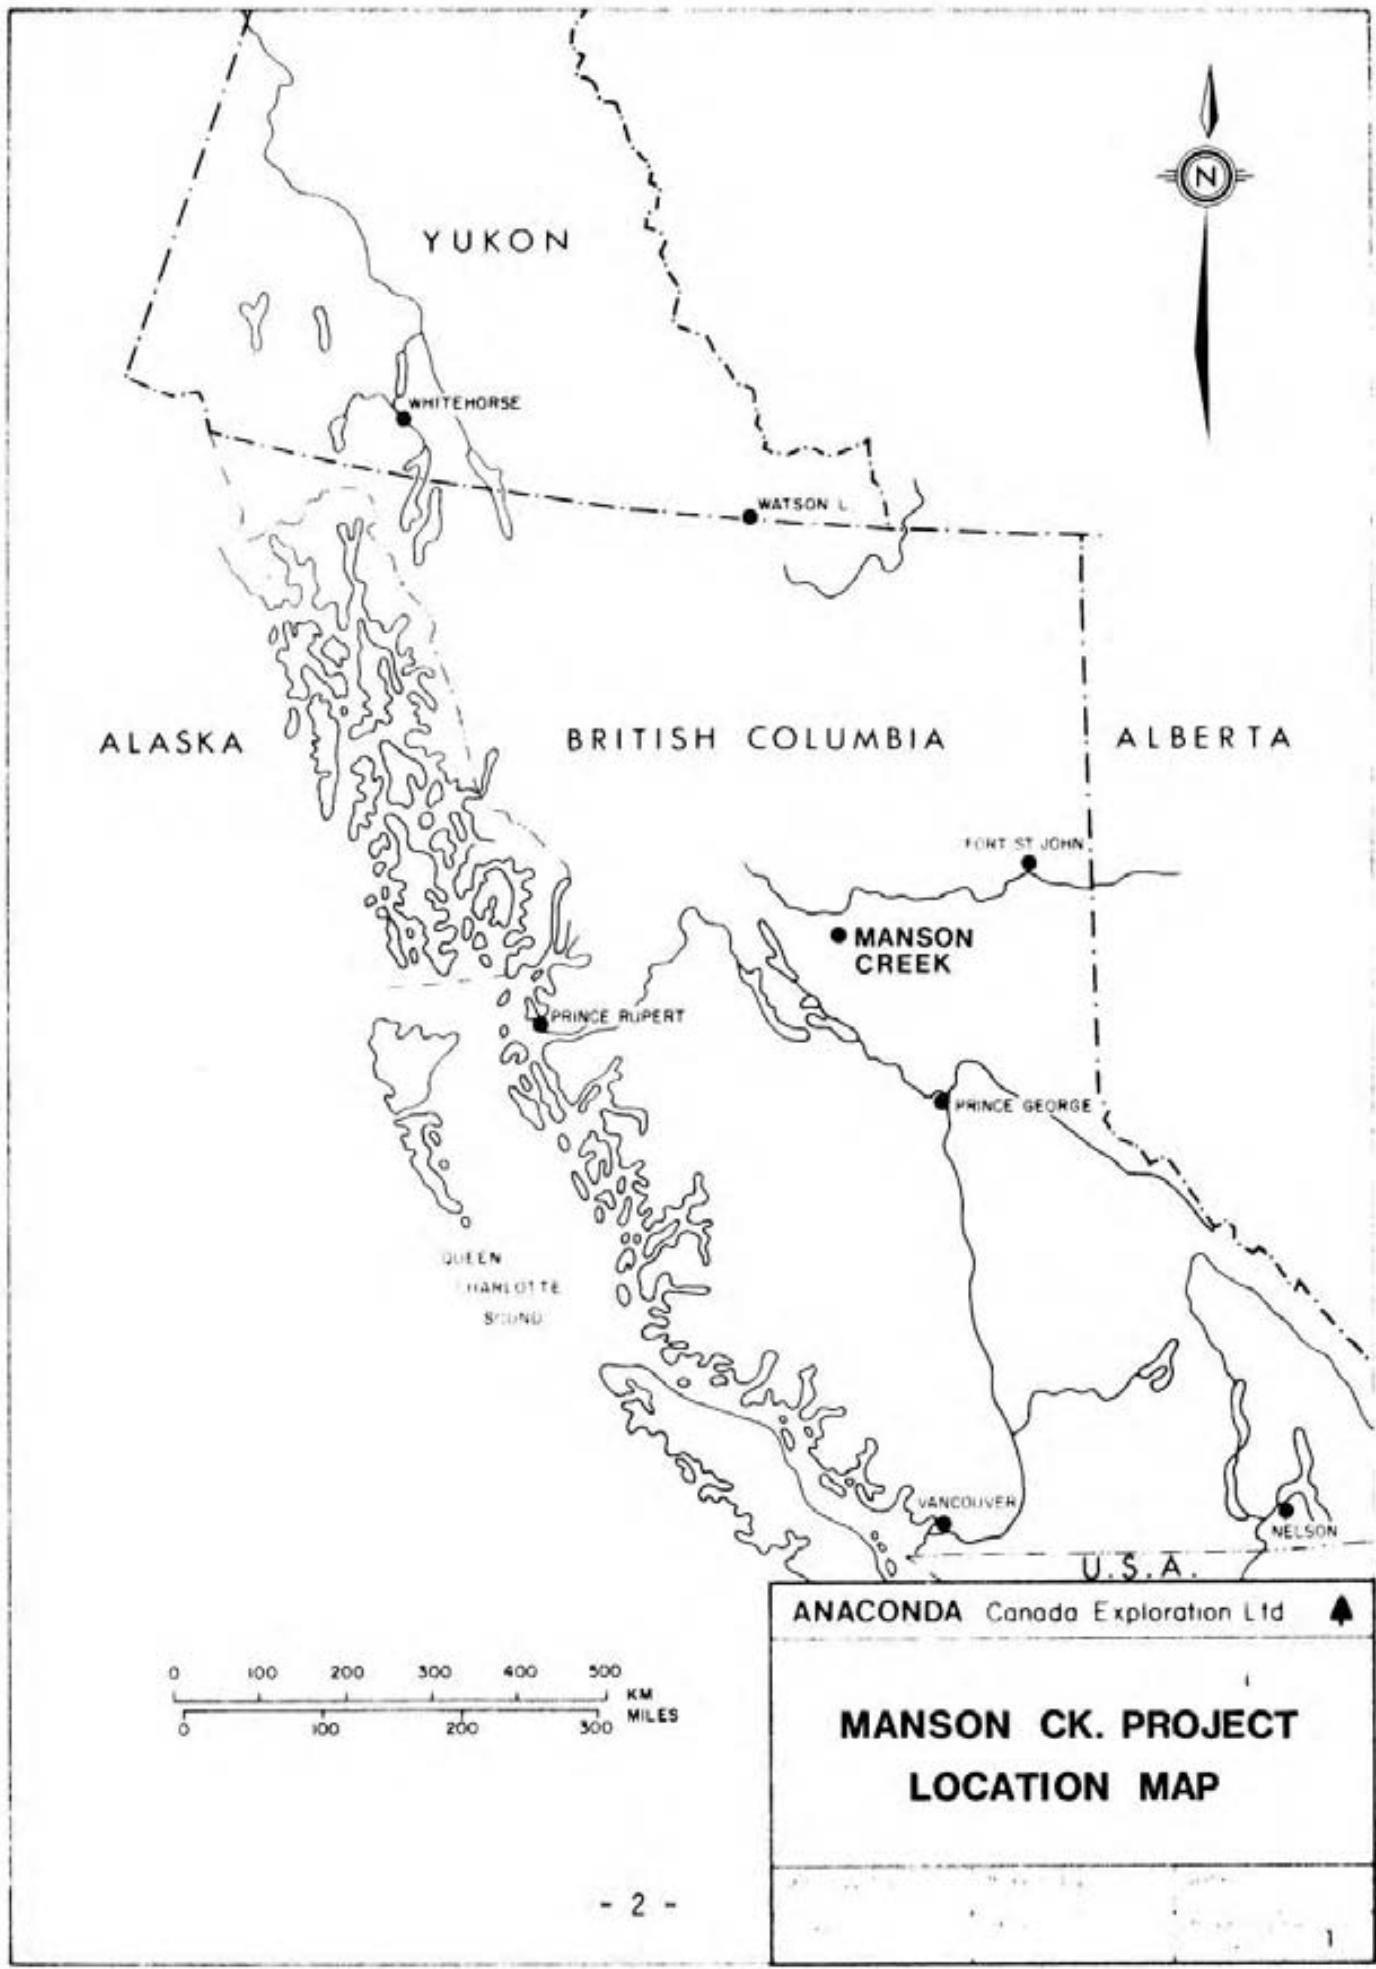

The property is located approximately 240 kilometers northwest of Prince George, B.C. (Figure 1, page 2), at latitude 55°40'N and longitude 124°30'W, on the north slope of Blackjack Mountain.

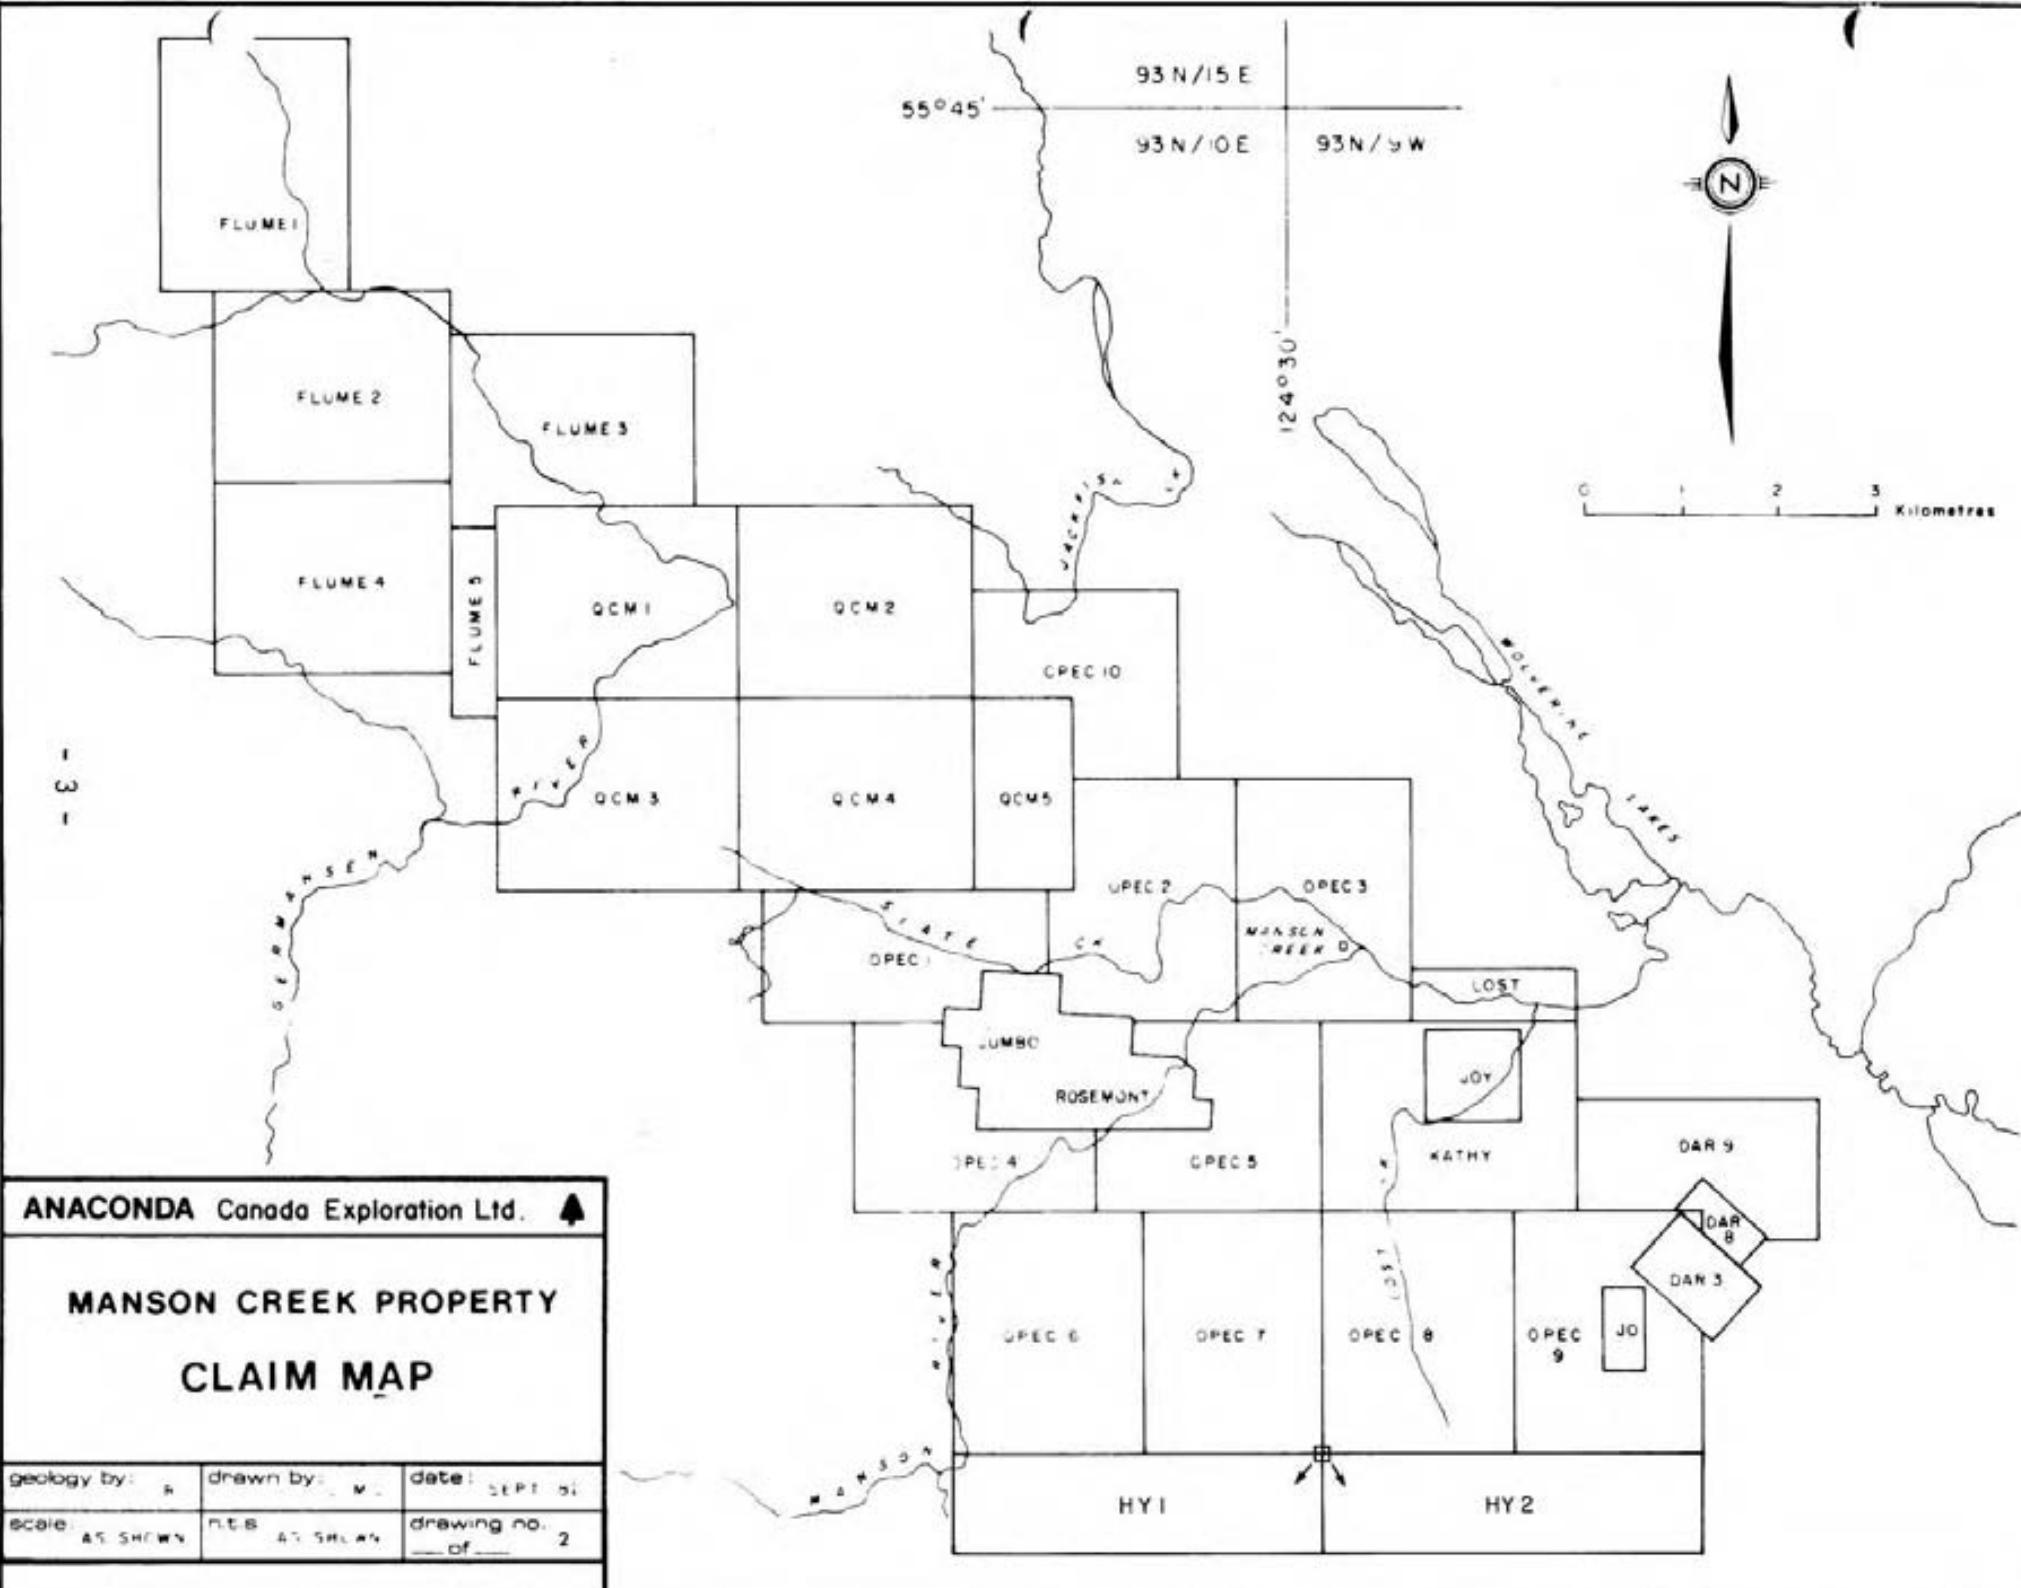

Closest settlement is the town of Manson Creek which can be reached by gravel road from Fort St. James, a distance of approximately 225 km. From Manson Creek access to the claims is either by foot (1-2 hour walk from the base of Blackjack Mountain) or via helicopter. Nearest helicopter base is Mackenzie, 100 air km southeast of Manson Creek.

PROPERTY

The claims (Figure 2, page 3) are located in the Omineca Mining Division. They are recorded as follows:

Claim Name	Units	Record Number	Date of Record
Opec 6	20	2554	February 25, 1980
Opec 7	20	2556	February 25, 1980
Opec 8	20	2557	February 25, 1980
Opec 9	20	2558	February 25, 1980
Hy 1	16	5088	April 6, 1983
Hy 2	16	5089	April 6, 1983

REGIONAL GEOLOGY

The claims lie within the Omineca Geoanticline of the Canadian Cordillera, (Figure 3, page 5), in Nina Creek Group rocks interpreted to be of Pennsylvanian to Permian age, (Monger & Paterson, 1974). The Nina Creek Group is in fault contact with Takla Group alkalic volcanic rocks on the west and the Lower Cambrian-Proterozoic Wolverine Complex metamorphic rocks in the east.

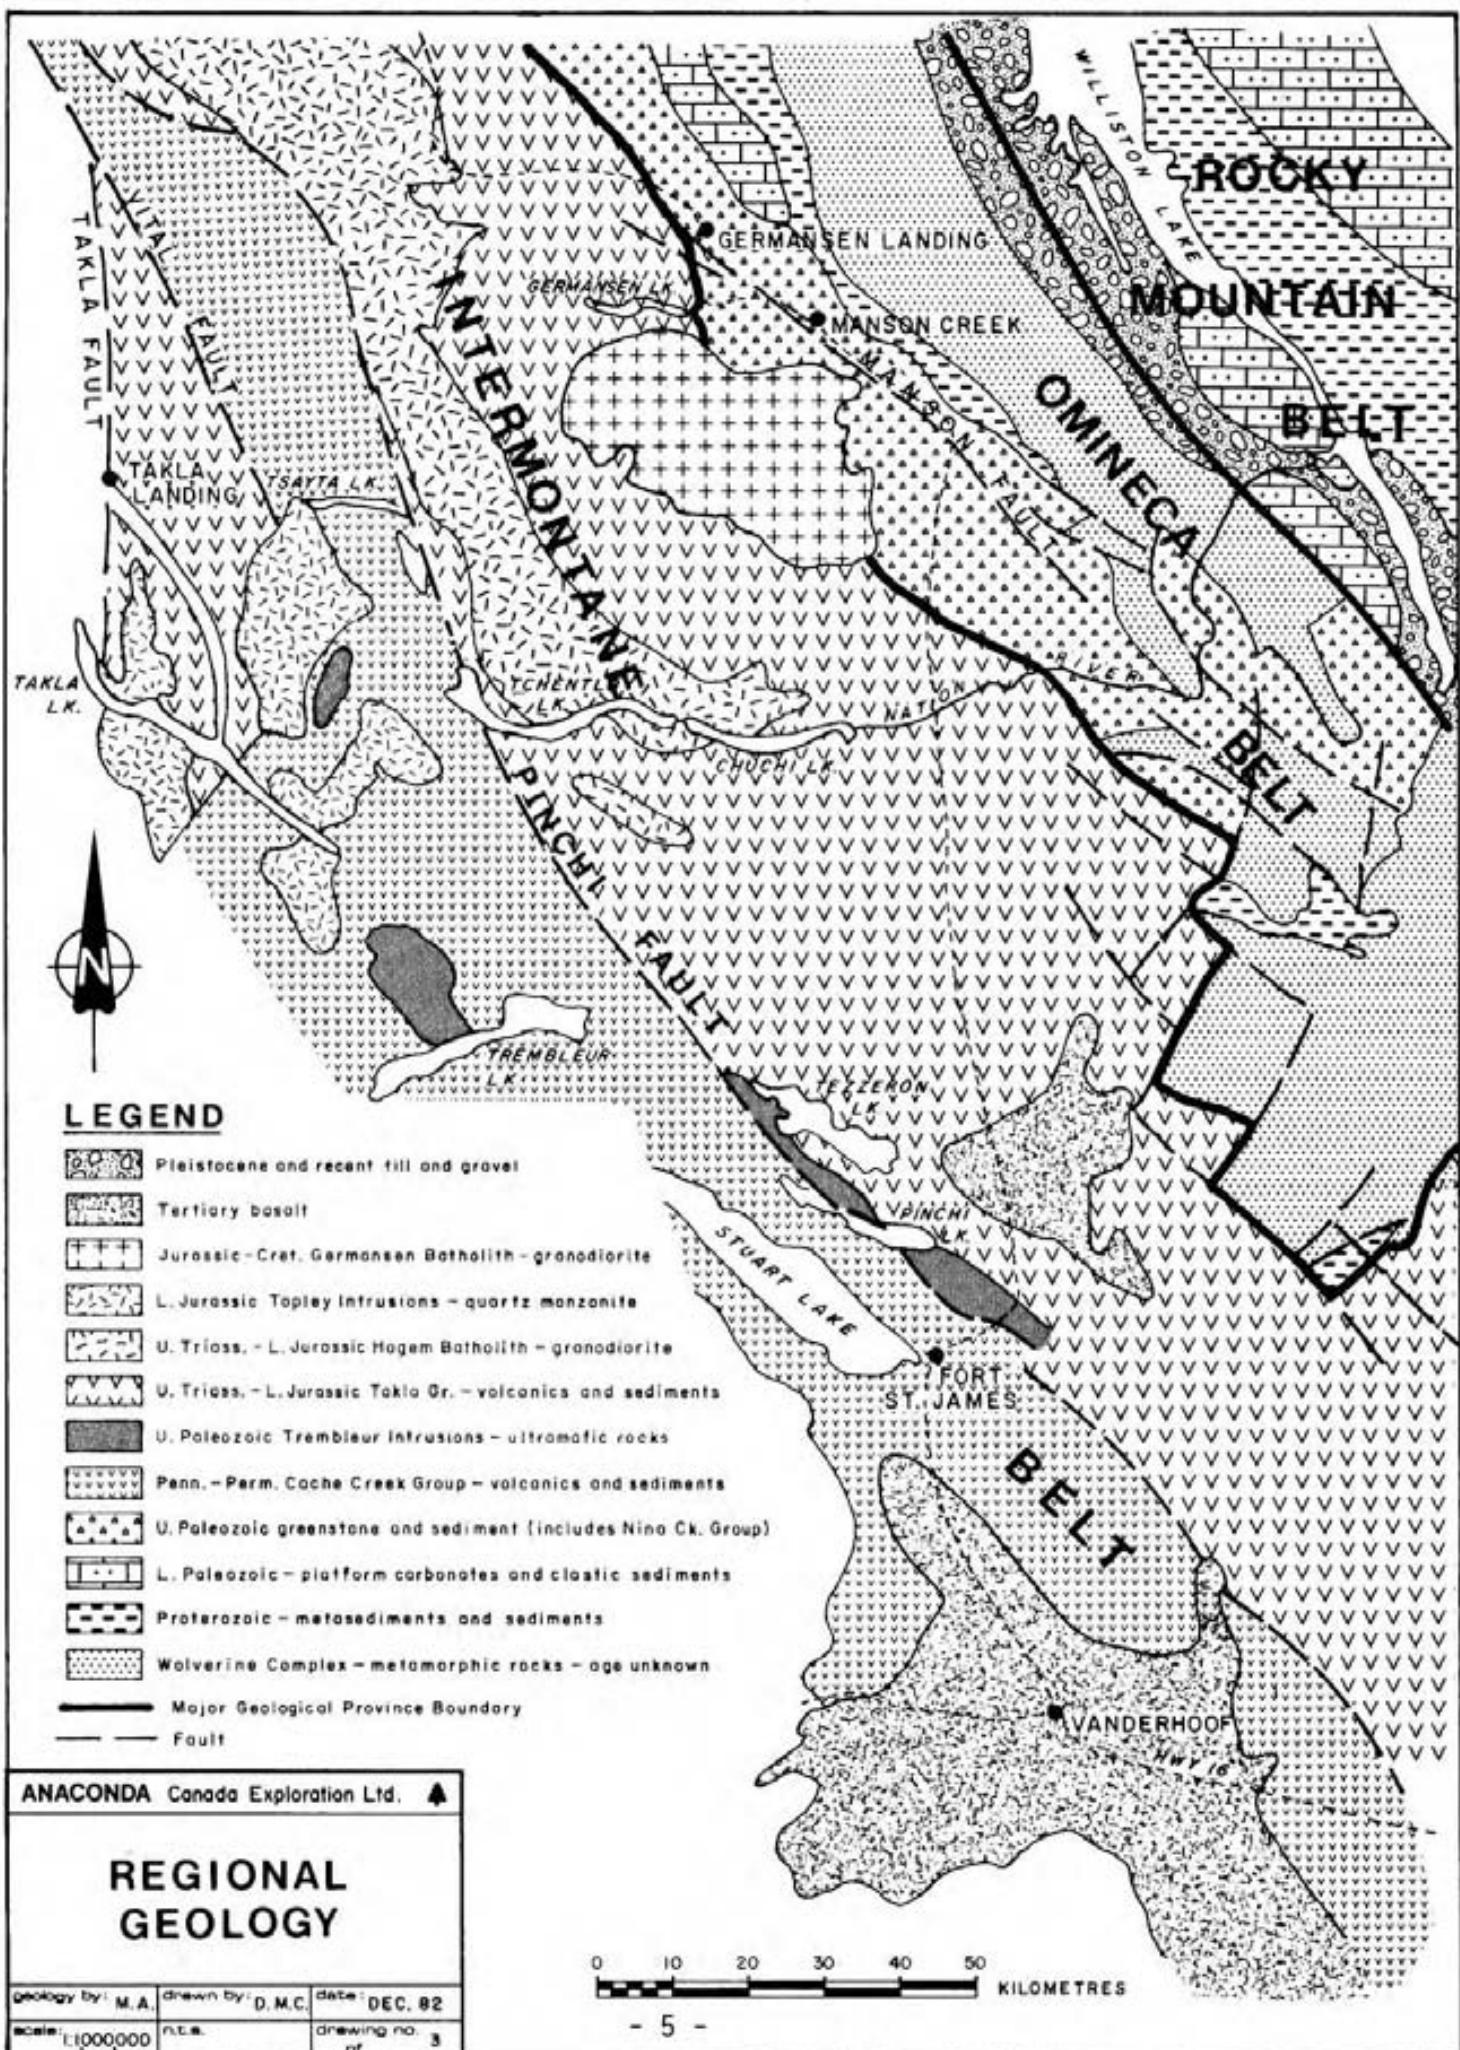

The Manson Fault zone cuts and/or is the western boundary of the Nina Creek Group over at least 40 km. It is marked by ultramafic rocks and their carbonatized equivalents and by a prominent aeromagnetic high trending approximately 120°.

The lower member of the Pennsylvanian-Permian package is predominately chert and clastic sedimentary rock with minor limestone, while the upper member is a thick mafic volcanic pile typically massive, rarely pillowled and containing thin tuff and volcanic breccia horizons (Monger & Paterson 1974).

The Germansen-Manson River area has been an active placer camp since gold was discovered on the Germansen River in 1870. The most productive rivers have been Germansen and Manson Rivers and Slate, Lost, Blackjack and Kildare Creeks. Armstrong (1949) noted the general spatial relationship of the gold bearing creeks and the Manson Fault zone.

SUMMARY OF 1983 PROGRAM

Two chained and flagged grid (Figure 4, In pocket) totalling 33 line kilometers were established along the Germansen Batholith-metasediment contact to follow-up on regional tungsten soil anomalies (>10 ppm W) outlined in 1982 (Ass. Rep. 10746). The grids were covered with geological mapping (1:5000 scale), soil sampling (519 samples collected) at 50 and 25 m intervals, and ground magnetometer surveys.

While establishing the East Zone grid, an old blasted silicified and pyritized outcrop with epithermal characteristics was discovered. A few grab samples were collected and returned geochemically anomalous (hundreds of ppb Au) gold values. As a result, a program of detailed geological mapping (1:2500 scale), rock and soil sampling, and VLF-EM was initiated to evaluate its mineral potential. Nine rock and 153 soil samples were collected from the epithermal zone.

EAST ZONE

Geology

Outcrops within the East Zone are confined to the southeastern portion of the grid between Lines 6E and 20E (Figure 5, In pocket). This area is centered along the contact between the Cretaceous Germansen batholith and psammitic (quartz-muscovite schist, Unit 1) and semi-pelitic (quartz-biotite schist, Unit 2) Paleozoic metasediments.

Quartz biotite schists form a hornfelsic halo surrounding the batholith along the eastern margin of the map area. They are strongly foliated, finely laminated, and contain calcareous intercalations which are converted to skarn assemblages (Unit 3) near the contact with the intrusives. The skarn portion of the hornfelsic package consist of light green layers (0.5 to 5 cm thick) intercalated with finely laminated biotite, amphibole, and quartz layers. The skarny layers contain diopside, pale garnet, epidote, and minor quartz. Minor disseminated pyrrhotite and magnetite are present in the melanocratic layers. Layering in the skarn bearing sequence dips at shallow angles to the south (5° - 10°). In contrast, the schistosity in both muscovite and biotite schists is invariably steeply dipping to subvertical.

Granitic phases within the map area are invariably leucocratic, equigranular, and consist of equal proportions of quartz, kspar, subordinate plagioclase, and up to 5-10% biotite (Unit 5) or biotite-muscovite (Unit 6). Hololeucocratic, medium to fine grained, muscovite-granite (Unit 7) patches are erratically distributed through

the main granite mass. Quartz-feldspar-muscovite pegmatite dykes, locally with well developed graphic intergrowths, commonly transect the granite.

A hydrothermally altered silicified zone with epithermal characteristics occurs near the granite-sediment contact between lines 8E and 10E (Figure 4, pocket). This area is described in detail in a later section.

Soil Geochemistry - Tungsten East Zone Grid

Two hundred and nineteen soils were collected from the West Zone, predominantly from a residual reddish, clay rich, Bf soil horizon, taken at average depth of 20 to 40 cm. Swampy and boggy areas were not sampled. Field notes on the sample and sample site were recorded at each station. The soils were collected in numbered wet-strength Kraft sample bags and air dried prior to shipment to Bondar Clegg Labs of North Vancouver. Analyses for W were determined by DCP methods on soil lines east of 13E and by colourimetric methods to the west. Details on sample preparation and analytical techniques are given in Appendix I. Soil sample locations are shown in Figure 5 (pocket) and analytical results listed in Appendix II. Soil sample results are presented in Figure 6 (pocket).

Raw geochemical data were assessed through a systematic application of standard procedures which consist of:

- (1) Calculation of summary statistics (both for arithmetic and log transformed data - Appendix III).
- (2) Determination of contour intervals from analysis of appropriate arithmetic or logarithmic histograms (Appendix III) and probability plots.
- (3) Contouring of threshold level metal concentrations and highlighting of very anomalous samples on a geochemical map.

Results

Tungsten

Tungsten variability obtained is relatively low for both analytical methods as evidenced by their restrictive ranges (1-16 ppm W and 2-30 ppm W) for the DCP and colorimetric techniques, respectively. Colorimetrically determined W highs of 13 and 16 ppm on L20E are probably related to weak skarn mineralization. DCP determined W highs of greater than 10 ppm W tend to cluster and coincide with patchy zones of intense to moderate silicification and quartz veining proximal to the contact between granite and quartz muscovite schist.

Tin

Tin values on the East Zone range from 1 to 11 ppm with more than 90% of the distribution being less than 5 ppm. As a consequence, the spatial distribution of high and low values is intermixed and no discernible pattern is recognized.

Magnetometer Survey

A total field magnetometer survey was completed over the East Zone grid. Readings were taken at a station interval of 25 meters on crosslines separated by 200 meters. Some fill in to a 100 meter interline spacing was performed in the eastern-most portion of the grid. A Geometrics Unimag II was used for the survey, and readings were corrected for diurnal drift by reference to base station readings with a Unimag I at half hour intervals. The base station was located at the camp.

The results of the magnetometer survey are presented in contour plan form in Figure 8 (pocket). The narrow high amplitude magnetic high located at 4+25S on line 19E is coincident with magnetite skarn at a granitic contact. The magnetic high located at 1S on line 16E is coincident with a magnetite bearing biotite schist. Other magnetic highs on the East Zone grid (such as Line 20W/station 0+50S; Line 18W/stations 1N to 2+50N; Line 14W/station 0+25N; Line 8W/stations 1N, 2+50N, and 4N;

Line 4W/station 2N; Line 2W/station 1+25S; and Line 10E/stations 1+75N to 2+25N) occur in areas where no outcrop was located. Their source may be inferred as either skarn or biotite schist.

EPIHERMAL ZONE

Geology

Epithermal mineralization occurs in a WNW trending, 30 m wide zone of aplite, quartz muscovite, pegmatite, and patchy silica flooding and brecciation which straddles the contact between biotite-muscovite phases of the Germansen Batholith and surrounding quartz-muscovite schists (Figure 9, pocket). A WNW trending, 6 m wide aplite sill also occurs 75 m north of the main granite contact. The contact between the epithermal zone and the metasediments is gradational and conformable. It is characterized by a decrease in silicification and corresponding increase in schistosity away from the zone. The contact between the epithermal zone and the batholith is obscured by residual overburden.

The epithermal zone is exposed over a strike length of 400 m and disappears beneath overburden in both directions. A NE trending fault, subparallel to the dominant joint direction in the granite, apparently offsets the zone between lines 9E and 10E.

Rock Geochemistry-Mineralization

Nine rock samples were collected from the epithermal zone and analyzed by fire assay and AA for Au and Ag. Six of these samples were also analyzed by DCP for a suite of trace elements. Sample locations and Au results are shown in Figure 9, (pocket). Trace element data are shown in Table 1 (p.7).

Gold values (up to 440 ppb Au) occur in intensely silicified portions of the epithermal zone containing aggregates of massive, white, beige, and grey coloured fine grained to cryptocrystalline (chalcedonic) quartz. The quartz is locally brecciated, rebrecciated, and healed with vuggy

TABLE I
MANSON CREEK PROJECT
Epithermal Zone
Rock Geochemistry

quartz. Pyrite (up to 2%) and minor stibnite occur locally as disseminations or aggregates interstitial to brecciated quartz fragments.

Multielement geochemical data (Table 1) show the epithermal zone to be associated with geochemically anomalous Sb, As, Cr (127-388 ppm) concentrations, erratically high W values (up to 60 ppm) and sporadic high Pb-Sn contents (667 and 70 ppm, respectively).

Soil Geochemistry

A detailed soil sampling program was carried out in order to assess the geology and metal potential of the contact area between granite and quartz-mica schists.

153 samples were taken over the Epithermal Zone Grid which measured 600 x 300 metres. Soils were collected at 25 metre intervals on lines spaced 50 apart. Most of the samples were taken at an average depth of 20 to 40 cm from a moderately well developed residual Bf horizon employing sampling procedures previously described. The remaining samples were obtained from the C horizon. Organic rich samples were excluded.

Sampling Procedures

Analyses for Au, Ag, As, Sb, and Mn were carried out by DCP methods. Details on sample preparation and analytical techniques are given in Appendix I. Soil sample locations and Au-As-Sb geochemistry are shown in Figure 10 (pocket). Analytical results are listed in Appendix II.

Raw geochemical data were assessed through a systematic application of standard procedures previously described.

Results

Gold

Four major areas of gold accumulation (>20 ppb) are found on the Epithermal Zone. Two of them, one located to the extreme northeast and the other in the centre of the grid (Figure 33) have their axis parallel to the zone of quartz veining and silicification and contain gold values in excess of 150 ppb and up to 535 ppb. The two peripheral zones are open at their respective grid boundaries.

Arsenic

The distribution of arsenic-rich soils is more widespread than that for gold. Three of the gold anomalies are also arsenic-rich. These zones are characterized by accumulations of arsenic from 40 to 509 ppm with an average value of >100 ppm.

Antimony

Antimony rich soils tend to reflect the contact zone between the quartz muscovite schist and intrusive rocks. Their distribution to the northwest coincides with anomalous gold and arsenic. Generally the outlined anomalous zone averages greater than 80 ppm (maximum value 408 ppm).

Silver

Silver contents are typically very low, ranging from detection limit levels of .2 ppm to a high of 2.0 ppm. Their distribution is sporadic and elevated concentrations of silver do not correlate with anomalous concentrations of other metals.

VLF Survey

A VLF survey was completed from the baseline to 3S on lines 6E to 10E, and 12E covering the Epithermal Zone. Stations were read at 25 meter

Intervals using Cutler, Maine (NAA) as the primary VLF field. The in phase tilt angle values are plotted as line profiles, and the horizontal component of the field strength in contour plan form, in Figure 11 (pocket).

A weak VLF conductor was defined in line 8E near station 1+25S. The conductor trends grid east west to lines 7E and 9E, and lies in an area of background magnetic field strength (see magnetic field contour plan, East Zone grid, Figure 8, in pocket).

TUNGSTEN WEST ZONE

INTRODUCTION

A program consisting of geological mapping, soil sampling, magnetometer survey, and ultra-violet prospecting was performed to assess tungsten anomalies (>20 ppm) obtained from a 1982 regional soil survey on the OPEC 6 claims. Geological reconnaissance during grid construction confirmed the lack of visible outcrop as evidenced in previous year's work. The overburden in the area is generally believed to be a relatively shallow lodgement till (3 to 10 m ?) slightly complicated by mass wasting along steep slopes. Despite the overburden coverage, detection of a mechanical dispersion pattern of W by soil sampling the appropriate soil horizon was deemed a viable exploration tool in this geochemical landscape.

Soil Geochemistry

300 soil samples were collected from the West Zone predominantly from the Bf and Bt soil horizon taken at an average depth of 20 to 40 cm, employing the same sampling techniques as previously described. Swamps and boggy areas were not sampled. 53 samples from the centre of the previously outlined reconnaissance W soil anomalies were selected and analyzed for W using both pulverized and unpulverized -80 mesh fractions. Soil sample location and analytical results are shown in Figures 12 and 13 (pocket) respectively. Geochemical data were assessed

through a systematic application of standard procedures previously described. Analytical results are listed in Appendix II. Summary statistics and histograms are listed in Appendix III.

Results

The distribution of tungsten in soils exhibits a large variability with values ranging from 3 to 360 ppm W, averaging about 18 ppm. Despite the high variability, anomalous areas (>40 ppm) were easily distinguishable from background areas. A continuous zone measuring 300 by 75 metres trending northeast to southwest over 4 soil lines averaged greater than 40 ppm W and contained many values in excess of 100 ppm W (Figure 13, pocket). Locally derived skarn-float failed to fluoresce in short wave ultra-violet light. However, it appears that the UV lamp used in the field was defective. In contrast, -80 mesh fractions of soil material lamped at the lab in the fall, fluoresced brilliantly.

A comparison of pulverized and unpulverized -80 mesh sieved fractions revealed that geochemical contrast is much improved in the latter.

Magnetometer Survey

A total field magnetometer survey was completed over the West Zone grid. Stations were read at 25 meter intervals along crosslines at 100 meter interline spacing. A geometrics Unimag II was used on the survey, and readings were corrected for diurnal drift by reference to base station readings taken at the camp with a Unimag I at half hour intervals.

The results of the magnetometer survey are presented in contour plan form in Figure 14 (pocket). The plotted values should be multiplied by 10 and have 50000 gammas added to obtain the magnetic field value of shading on the contour plan:

- dark shading - greater than 58,700 gammas
- light shading - 58,500 to 58,700 gammas

Several discontinuous moderate to strong magnetic field highs were outlined on the West Zone grid, such as at Line 200E/station 125N, 200N,

and 325N; Line 500E/station 450S; Line 600E/station 125N and 425N; Line 700E/station 325S and 325N; Line 900E/station 425S; and Line 1100E/station 325S. These anomalies are well defined and correlate quite well from line to line, although often at a lower amplitude. Similar amplitude anomalies detected on the East Zone grid were coincident with biotite schist and magnetite skarn.

SUMMARY AND RECOMMENDATIONS

Several interesting features were discovered as a result of the 1983 follow-up work carried out on the south Opec and Hy claims.

1. Diopside-garnet endoskarns at the contact between Cretaceous intrusives and Paleozoic metasediments in the southeast corner of the East Zone grid.
2. Magnetic highs, possibly reflecting buried skarns, in both East and West Zone grids.
3. Strong W in soil geochemical anomalies (up to 360 ppm W) in the West Zone.
4. Anomalous gold (up to 440 ppb Au) values associated with high Sb-As-Cr-W concentrations in a quartz-flooded epithermal zone occurring within the East Zone grid along the Germansen Batholith-metasediment contact.

Although scheelite bearing outcrops were not discovered during the present survey, additional sampling and some hand trenching are recommended to further evaluate the West Zone tungsten anomalies.

A petrochemical study of skarns and granitic rocks is also warranted to a) determine if the skarn zones discovered in the East Zone could belong to potential tungsten-bearing skarns, and b) to investigate the Sn-W potential of S-type granitic phases bordering the Germansen Batholith.

Further soil and rock sampling followed by hand trenching is recommended to further evaluate the strike length extension of the epithermal zone.

APPENDIX I

ANALYTICAL PROCEDURES

- 1. Gold Analysis**
- 2. Multielement Analyses**
- 3. DCP Multielement Analyses**

QUALIFICATION OF ORGANIZATION

Bondar-Clegg & Company Ltd., is a proven organization of professional chemists, analysts and technicians offering a wide range of analytical services to industry, universities and government departments.

The organization acts as a check laboratories to both the United Nations and the Canadian International Development Agency. Many major mining, consulting and industrial firms, including Canadian government departments, are among the company's clientele.

The North Vancouver facility was established in 1966 and was expanded into new quarters in 1979.

LABORATORY FACILITIES AND EQUIPMENT

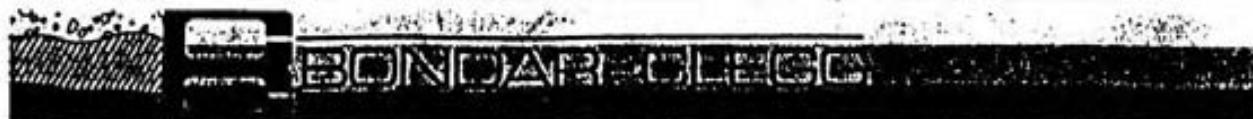

Bondar-Clegg's North Vancouver laboratory comprises some 10,000 square feet of office, laboratory and sample storage space, and is well equipped with the required scientific equipment and supplies.

The sample preparation equipment includes:

1. Primary (Jaw) crusher-reduces particle size to 1/2".
2. Secondary (Cone) crusher-reduces particle size to 1/8".
3. Jones riffle splitter.
4. Rins and rock pulverizer-reduces representative sample to 100 mesh.

With the major instruments being:

1. Techtron AAS
with Fisher Recordall 5000
2. Varian AA-1275
with 5150A thermal Printer by Hewlett-Packard
3. I. L. AA/Ae Spectrophotometer 751
with Digital printer
4. Techtron AA4
with Fisher Recordall 5000
5. Techtron AA6
with Fisher Recordall 5000
6. Jarrell - Ash fluorimeter
7. X-ray Fluorescence instrument (built by Bondar-Clegg Instrument Division)

GEOCHEMICAL SAMPLE FLOW

- STEP 1**
LOGGING IN - each sample submission is assigned a unique lot number
- STEP 2**
SORT - according to sample type (soils, streams, rocks, etc.) and then according to alphabetic and/or numeric order.
- physical sample is checked off against sample submittal form which has been completed (?) by the client.
- STEP 3**
SAMPLE PREPARATION - all samples are processed in numeric order with adequate drying being ensured before preparation
- a) soils-sediments - bag dry sample in the bag with rubber mallet to break loose fines from clods/mosses/etc.
- pour into 80 mesh stainless steel sieve.
- sift out all-80; if samples are for Au, sift out -20 +80 if -80 fraction less than 20 gm.
- re-bag sample and refile if retention of rejects requested otherwise - out goes the oversize
- b) rock and drill core - put in numerical order; insert made-up pulp bags into proper rock bag
- primary crush
- secondary crush (80% -10 mesh)
- split out 200 - 400 gm with a Jones riffle splitter
- pulverize via an impact (rind and puck) grinder.
Final product is about 50% -150 mesh and 99% -80 mesh, and is free from pulverizer contamination.
- c) pan concentrates - sample is pulverized in its entirety to ensure homogeneity
- Please no coarse metallic nuggets without prior warning
- d) pulps - spot check for proper preparation; if unacceptable we re-prep
- e) other sample types are prepared according to client's request
- STEP 4**
WEIGHING - using electronic balances, with a precision of +/-0.01g., we weigh 5% of the samples for duplicate analysis and 2% of our analyses are performed on accepted standards.
- STEP 5**
EXTRACTION METHODS - HNO₃-HCl - a vicious attack that satisfactorily leaches Cu Pb Zn Mo Ag Mn Cd Ni Co etc. in 'all' rocks and soils/ seds. Problems would be low level values (less 40 ppm) in high iron oxide soils or in tight refractory lattices

- 2 -

HN03 - satisfactory for almost all ore minerals of U, Bi some As minerals, and most sulphides.

PARTIAL EXTRACTIONS - specific for specific type occurrences or for loosely bonded(e.g. hydromorphically deposited) ions.

HN03-HC104-HF - a higher temperature, vicious attack that specifically attacks some refractory silicates and oxides. More difficult to control precision, but useful for elements like V, Be, Se and certain low level metallics in rock geochem programs.

HBr-Br - a slow, but powerful oxidative attack designed for Te and Tl minerals.

VARIOUS FUSIONS - for difficult to handle elements in refractory lattices (e.g. W Cr Au Pt).

STEP 6
ANALYSIS - (see attached sheet)

STEP 7
DATA APPROVAL AND TRANSFER - (see accompanying sheet entitled Computer services)

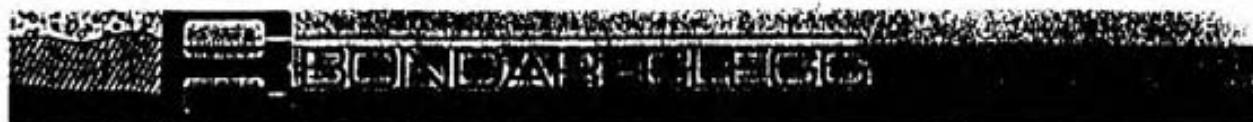

STEP 8
QUALITY CONTROL - fifteen percent of our staff do nothing else but supervise and check procedures and techniques. The resident assayer, chemist and geochemist provide the final check.

ANACONDA CANADA EXPLORATION LTD.

Please note that in 1983 your Au assays were analyzed by classic fire assay at 0.5 assay ton (14.58g) and 1 assay ton (29.166g) depending on the fusability of the samples being analyzed. The dore bead (combined AuAg) was then dissolved and run on A.A. for Au. High Au's (over 0.20 OPT) were checked by re assay and finished by the classical method of weighing the Au bead taken from the sample.

NOTE: - Geochem Au is run on 20gms of sample.

GEOCHEMICAL METHODS

ELEMENT	EXTRACTION	METHOD OF ANALYSIS
Cu, Pb, Zn, Mo, As, Cd, Ni, Co, Mn, Fe	Hot Lefort Aqua Regia	Atomic Absorption
U	Hot Conc HNO ₃	Fluorimetric
<u>H</u>	Basic Oxidation Fusion	Colourimetric
F	Basic Fusion	Citrate Buffer-Specific Ion
<u>Au, Pt, Pd</u>	Fire Assay + Hot Aqua Regia	Atomic Absorption
<u>As</u>	HC104-HNO ₃ Arsine	Colourimetric
Hg	Aqua Regia	Closed Cell, Flameless Atomic Absorption
<u>Sn, Sb, Ba, Rb, Sr, Y</u> <u>Zr, Nb, La, Ce, Ti</u>		Energy dispersive XRF
Th, Se, Ta, Ga, In		Discrete angle/cathode XRF
Bi	Hot Conc HNO ₃	Atomic Absorption
V, Be, Li	HC104-HNO ₃ -HF	Atomic Absorption
Cr	Sodium Peroxide Fusion	Atomic Absorption
Tl, Te	HBr-Br + Organic Extraction	Atomic Absorption
B	Basic Fusion	Plasma
Re	Alkali Fusion + Organic Extraction	Atomic Absorption
C		Leco Induction Furnace
WHOLE ROCK ANALYSIS		
SiO ₂ K ₂ O Na ₂ O CaO		
MgO MnO Fe Al ₂ O ₃	HF-HNO ₃	Atomic Absorption
TiO ₂ P ₂ O ₅	HF-HNO ₃	Colourimetric
S		Leco Induction Furnace

Fraction used for analysis: Rocks -100 mesh; soils/sediments -80 unless otherwise noted.

DIRECT CURRENT PLASMA EMISSION SPECTROSCOPY

=====

INSTRUMENTATION:

MAKE: SPECTRAMETRICS

MODEL: SPECTRASPAN III B

THEORY OF OPERATION:

The fluid sample is introduced as an aerosol and enters the direct current argon plasma which serves as a high temperature (5000 to 6000 degree K) excitation source. The emission lights of the atoms (or Ions) enter the optical module with echelle grating for high resolution and reach the detector module capable of simultaneous multi-element measurement.

SAMPLE DISSOLUTION:

MAJOR OXIDES WHOLE ROCK ANALYSIS:

Sample pulp is fused with Lithium Tetraborate and dissolved in 6 percent nitric acid.

MINOR OXIDES AND TRACE METAL ELEMENTS BY TOTAL ACID DISSOLUTION:

Sample pulp is treated with HF, HCl, HNO₃ and HClO₄ and heated to fuming. The nearly dry sample mixture is dissolved in dilute HCl and HNO₃.
