### INTRODUCTION

During November of 1983, Glen E. White Geophysical Consulting and Services Ltd. conducted a program of vector pulse electromagnetometer surveying on the KAMAD 7 claims on behalf of O.K. Ore Processing Ltd. This survey consisted of 17 kilometres of coverage from three transmitter loop setups. The objective of the survey is to delineate conductor trends and infer attributes of position, depth and dip.

Immediately upon completion of the survey diamond drill holes were spotted and three conductor trends were drilled. The first of these drillholes was tested with the downhole pulse electromagnetometer technique with the objective of detecting an off-hole source beneath the strong intersected conductor.

The KAMAD 7 claims are situated in the Adams Lake area near Sinmax Creek, approximately 70 km northeast of Kamloops, British Columbia.

### VECTOR PULSE ELECTROMAGNETOMETER SURVEY

The Crone pulse electromagnetometer system is a time domain E.M. system which can be used in the standard horizontal loop mode, fixed source mode or in a downhole mode.

The primary field for the standard horizontal loop method is produced by a portable transmitter loop of 6, 10, or 50 metres diameter. A depth of search of approximately 75% of separation is obtainable due to the high sensitivity of the receiver system. As measurements of the time derivative of the secondary field occur during primary field off time the method is relatively free from geometrical restrictions. Interpretation is accomplished with the aid of Slingram horizontal loop curves.

The primary field for the 2000 watt fixed source system is provided by a 500 by 1000 metre transmitter loop. A 150 by 150 metre loop is utilized with the 500 watt system. The time derivative of the secondary field resulting from the presence of a conductor is sampled at eight windows on the decay curve, during primary field off time. These eight channels of secondary field information are equivalent to a wide spectrum of frequencies from approximately 2 KHz to 16 Hz thus allowing conductor character and strength determination. The vertical and horizontal components are obtained at each station on the traverse, using the convention of vertical component positive upwards and horizontal component positive away from the transmitter loop. In areas of high surficial conductivity the primary field on time of 10.8 ms, and the receiver delay times may be doubled in order to obtain late time information. Time synchronization between transmitter and receiver is by radio or cable link.

The apparent primary field information is recorded at each occupied station. Normalization of the data with respect to instrument gain produces a constant gain plot. In this format a vertical plate-like conductor anomaly would be symmetric. Normalization with respect to the apparent primary field at each station provides a constant primary field plot that is useful in recognizing conductors present in the far primary field and in correlating anomaly amplitudes from line to line. The anomalies lose symmetry in this format but the condition of anomaly amplitude dependence on distance from the loop is relaxed. In the case of stacked profiles on plan maps it is practical to use the advantages of both of these methods and plot a constant gain profile normalized to the apparent primary field at a station near the conductor axis. This facilitates the correlation of conductors from line to line at varying distance in coverage from several transmitter loops.

The vector focus method of data display is useful in some line source conductor conditions. A resultant vector can be obtained by the vector addition of the vertical and horizontal components of the primary field. A perpendicular to this resultant indicates the apparent eddy current position.

### BOREHOLE PULSE ELECTROMAGNETOMETER SURVEY

The borehole pulse EM system is a time domain down-hole EM instrument capable of detecting conductive mineralization intersected by the drillhole or lying offhole. The borehole pulse EM utilizes a special downhole receiver coil, 500m cable and winch gear in conjunction with the PEM receiver electronics and 500 watt transmitter apparatus normally employed in ground PEM surveys.

The primary field is produced by a 150 m square surface loop which is driven by the PEM transmitter with a 20 amp reversing pulsed current of 10.8 ms or 21.6 ms on to off time. The receiver obtains eight samples of the time derivative of the secondary field at times, on the 10.8 ms time base, ranging from .15 to 8.85 ms after primary field shut off.

Multiple transmitter loops may be used to provide various loop to conductor coupling geometries in order to obtain conductor attitude and position information. A complete survey of a given borehole may entail logging the hole from five transmitter loop setups. One of these loops would be approximately centered over the area of interest with the remaining four loops away from and distributed around the borehole.

When a conductor response is observed in a borehole log from a single transmitter loop, the nature of this anomaly allows the determination of the location of the conductive source relative to the drillhole. The response can indicate whether the borehole is intersecting the center of the conductor, the margin of a conductor, with the bulk of conductive material away from the hole, or

whether the conductor is entirely off-hole. In the case of a dike-like or tabular conductor, the magnitude of the anomaly obtained varies with the angle that the primary field cuts the conductor. Thus, the degree to which coupling is obtained to the conductor in coverage of a borehole from several loop setups will provide accurate information on the attitude and position of the conductive mineralization. Model study curves for various conductor to borehole geometries are employed in this interpretation from Dennis Woods M.A. thesis Queen's University, 1975. As well, computer plate modelling is supported for offhole cases. If the conductor tends towards a more spheroidal shape, the anomaly character will change, as well as its magnitude, when the primary field angle is altered. This occurs because the eddy currents are not constrained to flow within a conductive sheet. Thus, multiple transmitter loop coverage can also provide information on the shape of a conductive body.

In practice the responses observed in field situations are much more complex than those of simple models, but these results are sufficiently interpretable that the method has general acceptance and a number of discovery case histories exist.

## DISCUSSION OF RESULTS

### Vector Pulse Electromagnetometer Survey

The vector pulse E.M. data is displayed in component form in Figures 3-94. The information from transmitter loops A and C, which provide the best overall coverage of the zones have been used to produce the composite profile map illustrated on Figure 2. On this map the sum of the horizontal component and the first derivative filtered vertical component have been plotted such that anomalous responses occur as minima. Channels 2,4 and 6 have been selected to represent the secondary field decay behavior in order to provide an assessment of conductor quality.

The survey disclosed the presence of a number of conductors, from very strong eight channel responses of great depth extent to weak one or two channel anomalies.

These trends, illustrated on Figure 2, fall into two general systems of conductors: The western group, Conductors A-G show a general dip, where interpretable, of approximately  $40^{\circ}$  to the northeast. The eastern group, Conductors I,J appear to be somewhat steeper dipping, perhaps  $60^{\circ}$  to the northeast. In general both conductor groups tend to become more shallow towards the north of the grid.

The longest strike length feature is conductor A, which is traced over approximately 1500 metres, and remains open to the south. This major zone is flanked by somewhat weaker conductors which are traced over more

limited strike length. With respect to these flanking conductors' association to Conductor A, it may be inferred that Conductors G,D and E are stratigraphically related. As well, Conductors B and C and A and F are probably similarly related.

Conductors A,G and H undergo a termination between lines 100S and 200S and Conductor I is apparently off set. Although Conductors B and J are seemingly unaffected there is enough evidence to raise the possibility of cross fault disturbance to the zones in this area.

Conductor I is clearly manifested as a shallow early channel feature on lines 00N and 100S and weakens to the south. The zone appears as an inverted polarity response on 500S and 600S and is again clearly defined on 700S. The depth to the zone in this area is approximately 100 metres. To the south of this the influence of the conductor is felt in the last readings of 800S and 900S and the zone is clearly intercepted on line 1000S.

Conductor J is not observed to continue north of line 100S nor south of line 300S. The area of best response occurs near line 300S.

At the present time the anomalies associated with Conductors F,H and I remain open to the north and those of A,E and I remain open to the south.

### Borehole Pulse Electromagnetometer Survey

The Conductor A,C, and D area was tested by a diamond drillhole collared at 300E on line 700S drilled to the southwest at  $-70^{\circ}$ . This zone intersected strong graphite. The hole was logged from five transmitter loops in order to provide a range of primary field directions in order to assure coupling. A small loop test was also run to provide a test at higher induction numbers.

The responses observed, illustrated on Figures 95-100, show a strong intersected response centred on the 70 metre depth.

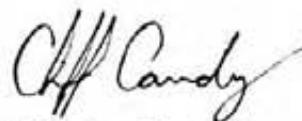

The response is of the usual intersected conductor type in the downdip loops, N and E, and in the inloop data. A reversed polarity response is evident from the updip loops, W and S. The overall response can be broken down into four discrete zones, the strongest of which occurs at 70 metres. The other features that make up the intersected graphite response, are best illustrated on Figure 97 and occur at 80, 95 and 110 metres. A very minor intersected response occurs at 160 metres in the inloop and E loop, Figures 95,97. No evidence of off-hole sulphide mineralization. As well, no end of hole response is evident which might result if a conductor were beyond the end of the hole.

SUMMARY AND CONCLUSIONS

Glen E. White Geophysical Consulting and Services Ltd. conducted a program of vector pulse electromagnetometer surveying and borehole pulse electromagnetometer surveying on the KAMAD 7 claims on behalf of O.K. Ore Processing Ltd. The vector pulse E.M. survey delineated eleven conductor trends in coverage from three transmitter loops. These trends were found to be northeasterly dipping with those to the southeast, of flatter dip. The conductors tend to become somewhat more shallow to the north.

The borehole pulse electromagnetometer survey shows a very strong response correlated with the graphite intersection in drillhole 1. No evidence was seen of conductive sources off-hole or beyond the end of the hole in the borehole logs.

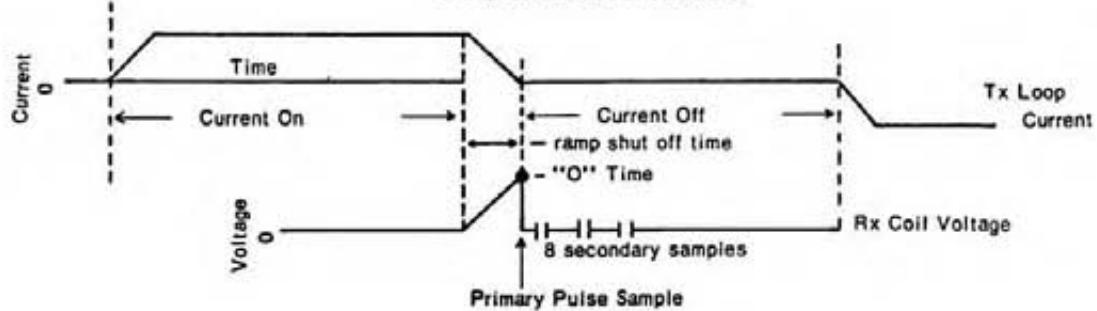

Respectfully submitted,

  
Cliff Candy B.Sc.,  
Geophysicist,

Glen E. White B.Sc., P.Eng.

## PEM SPECIFICATIONS

Current Off time: 9.4 ms

Current on time: 10.8 ms

Current shut off (ramp) time: 1.4 ms

Sample times (zero to centre of sample): .15ms, .45ms, .85ms, 1.45ms, 2.45ms, 3.75ms, 5.85ms, 8.85ms.

Sample width: 100  $\mu$ s

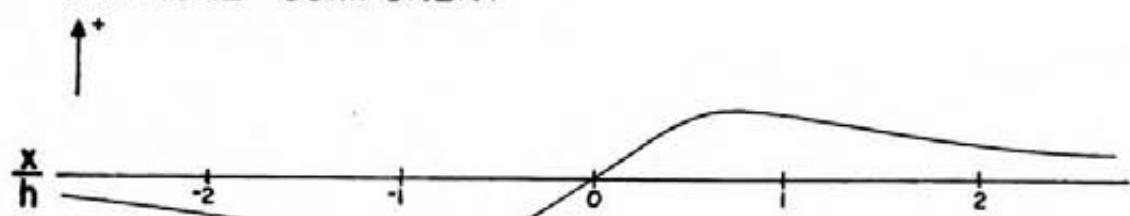

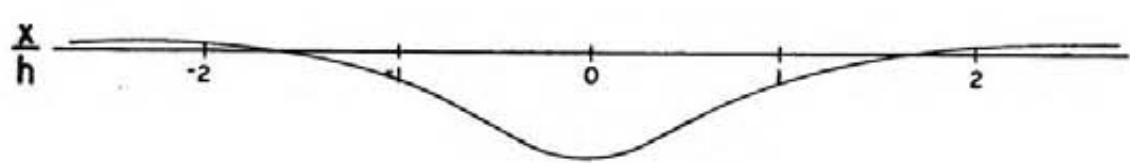

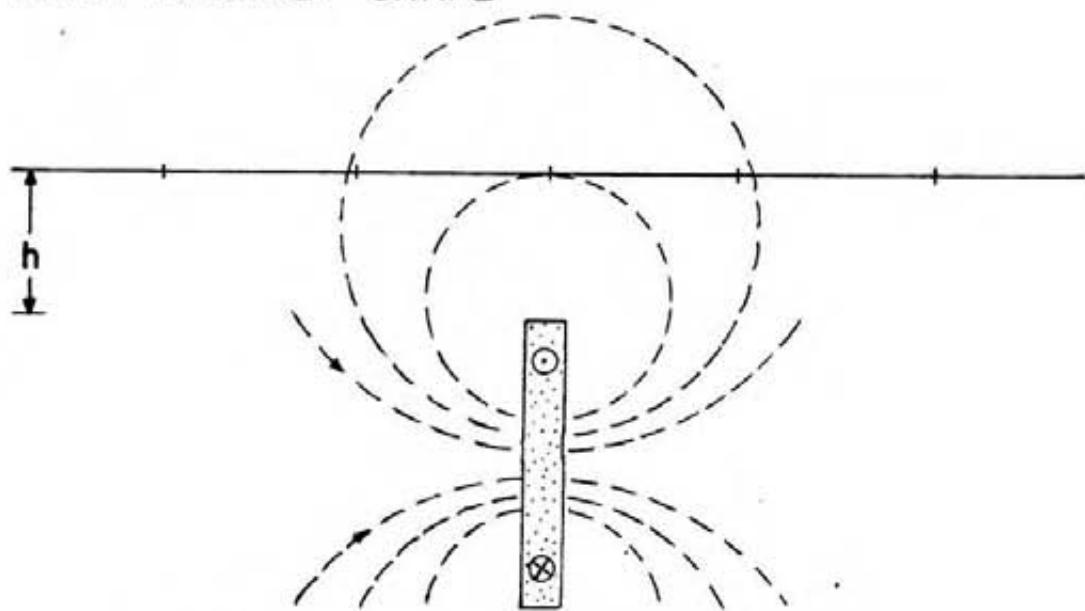

Zero time set at drop off point of primary pulse

**TRANSMITTER** — Transmitter power and loop size may be increased to obtain increased penetration. Weight, portability and power capabilities of the control instrument are the limiting factors. The standard transmitter is designed to be carried by two men.

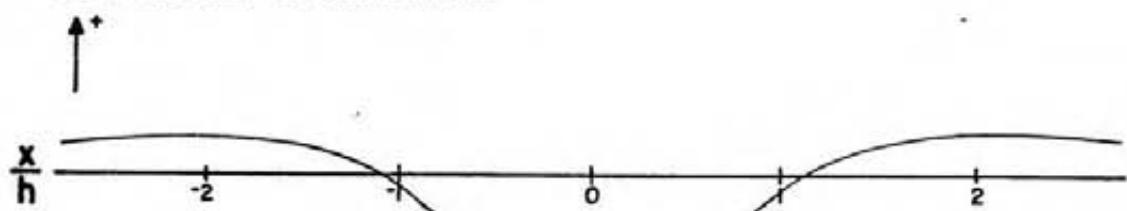

Loop diameter	— minimum 4 meters (13 feet)
Loop current	— 15 to 20 amps
Loop applied voltage	— 24 volts
Loop output	— minimum 4500 amps x meter <sup>2</sup>
Loop weight	— 11.8 kilos (26 lb)
Control unit weight	— 10 kilos (22 lb)
Control unit dimensions	— 20.5cm x 25.5cm x 36.5cm (8" x 10" x 14.5")
Battery supply weight	— 18.1 kilos (40 lb)
Battery supply	— 2 of 12 volt, 14 to 20 ampere hour
Timing control	by radio synchronization

**RECEIVER**

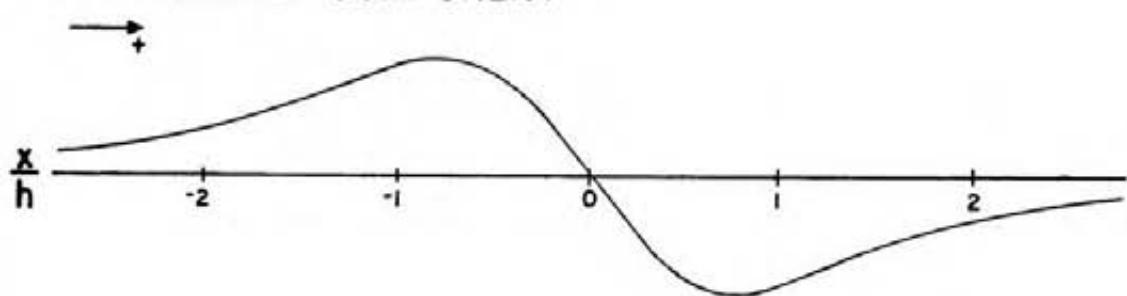

- Receive coil dimensions: 55cm x 15cm (22" x 6")
- Receive coil weight: 4.5 kilos (10 lb)
- Preamplifier in coil
- Preamplifier batteries: 2 of 9 volt
- Receive coil tripod mounted
- Receiver measuring instrument dimensions: 28cm x 18cm x 21.5cm (11" x 7" x 9")
- Receiver measuring instrument weight: 6.3 kilos (14 lb)
- Timing control by radio synchronization
- Primary sample width: 100  $\mu$ s
- Primary sample can be swept through primary pulse by means of a time calibrated pot
- Zero time set at primary pulse drop-off
- Secondary samples (eight of them) width: 100  $\mu$ s
- Secondary samples time (zero to middle of sample): (1) .15ms (2) .45ms  
(3) .85ms (4) 1.45ms (5) 2.45ms (6) 3.75ms (7) 5.85ms (8) 8.85ms
- Automatic sampling for 5 seconds then all samples automatically stored
- Sample read out by means of meter
- Continuous sampling possible by switching function switch to "Continuous"
- Noise can be monitored by switching function switch to "Noise"
- Battery supply: 24 volt rechargeable, 2 of 12 volt Gel GC 12-15

Vector Pulse Electromagnetometer Data Listing

O.K. ORE PROCESSING LTD. KAMAD 7 CLAIMS

Listing explanation:

Heading:

Line, Transmitter loop designator, Coordinates of loop perimeter and Survey date

Table:

STATION: Receiver station

V1-V8: Secondary field vertical component, positive upwards

H1-H8: Secondary field horizontal component, positive away from transmitter loop

Channel 1-8 sample times: .15, .45, .85, 1.45, 2.45, 3.75, 5.85, 8.85 milliseconds

G : Percent gain potentiometer setting, '1' indicates gain at 100%

PP: Percent 'primary field', '1' indicates setting at full scale,(100%)

GLEN E. WHITE Geophysical Consulting & Services Ltd.

November 29, 1983

Mr. L. McGregor,  
McGregor Construction,  
Box 150 Kamloops, B.C.  
V2C 5K3

Dear Larry:

Enclosed please find a progress invoice for the KAMAD project and a separate one for the VPEM test on your property.

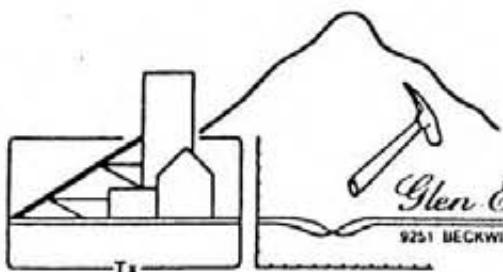

Pursuant to our telephone discussions we have recommended three preliminary diamond drill holes on the VPEM survey

- A) Line 700S-300E at  $-65^{\circ}$  S $45^{\circ}$ W
- B) Line 700S-700E at  $-60^{\circ}$  grid west
- C) Line 100S-300E at  $-70^{\circ}$  S $45^{\circ}$ W

The data is very interesting; complete line profiles and an interpretation report will be forwarded shortly.

Yours truly,

Glen E. White P.Eng.

PROJECT

Conduct large loop 2.0 kw vector pulse electromagnetometer surveying over Kumad 7 and OK 1 and 2 mineral claims as directed by Mr. Larry McGregor.

THE SURVEY

Glen E. White Geophysical Consulting & Services Ltd. will provide an experienced crew, equipment and vehicle for a fee of \$1200/day.

McGregor Construction will provide meals and accommodations.

Data processing at \$10/computer plot.

Interpretation maps and reports approximately \$2500.00.

The survey area is approximately 50 km which is some 10 days survey work.

It is understood that time is of the essence.
