INTRODUCTION

The Fall River property, consisting of claims Jo 1-6, 10-11, 105-106 and 110 (216 units) is located 35 km northeast of Takla Landing and 145 km northeast of Smithers in the Omineca Mining Division. Its National Topographic Survey location is 93 N/12 at 55° 44' north latitude and 125° 39' west longitude, (fig 1).

The property was evaluated using a Bell Jet Ranger 206B helicopter based at Takla Landing, a return trip taking 30 minutes.

The Property is characterized by Quartzite Creek and three other creeks draining from high ground, (1,750 m), along the southern margin of the property. The treeline is at about the 1,600 m elevation with alpine vegetation above and mixed coniferous vegetation, alpine fir and spruce, on valley sides and bottoms. Outcrop exposure is restricted to ridge crests, with maximum exposure present on north facing slopes.

Quartzite Creek has had a history of placer gold mining since the early 1930's. The main workings on the creek are situated 2.4 km above the confluence with the Fall River. The recorded production to 1950 is 435 ounces of gold and active operations continue to this day.

With the recent development of a new gold occurrence model involving large tonnage, low grade deposits, the owner, Impala Resources (U.S.) Ltd., contracted Golden Porphyrite Ltd., to locate the source rocks of the placer gold found in many of the surrounding creeks. Rocks belonging to the Permo-Triassic Cache Creek Group outcrop within and around the claim block and conform to this model.

FALL RIVER PROPERTY

OMINECA MINING DIVISION, B.C.

LOCATION MAP

KILOMETRES

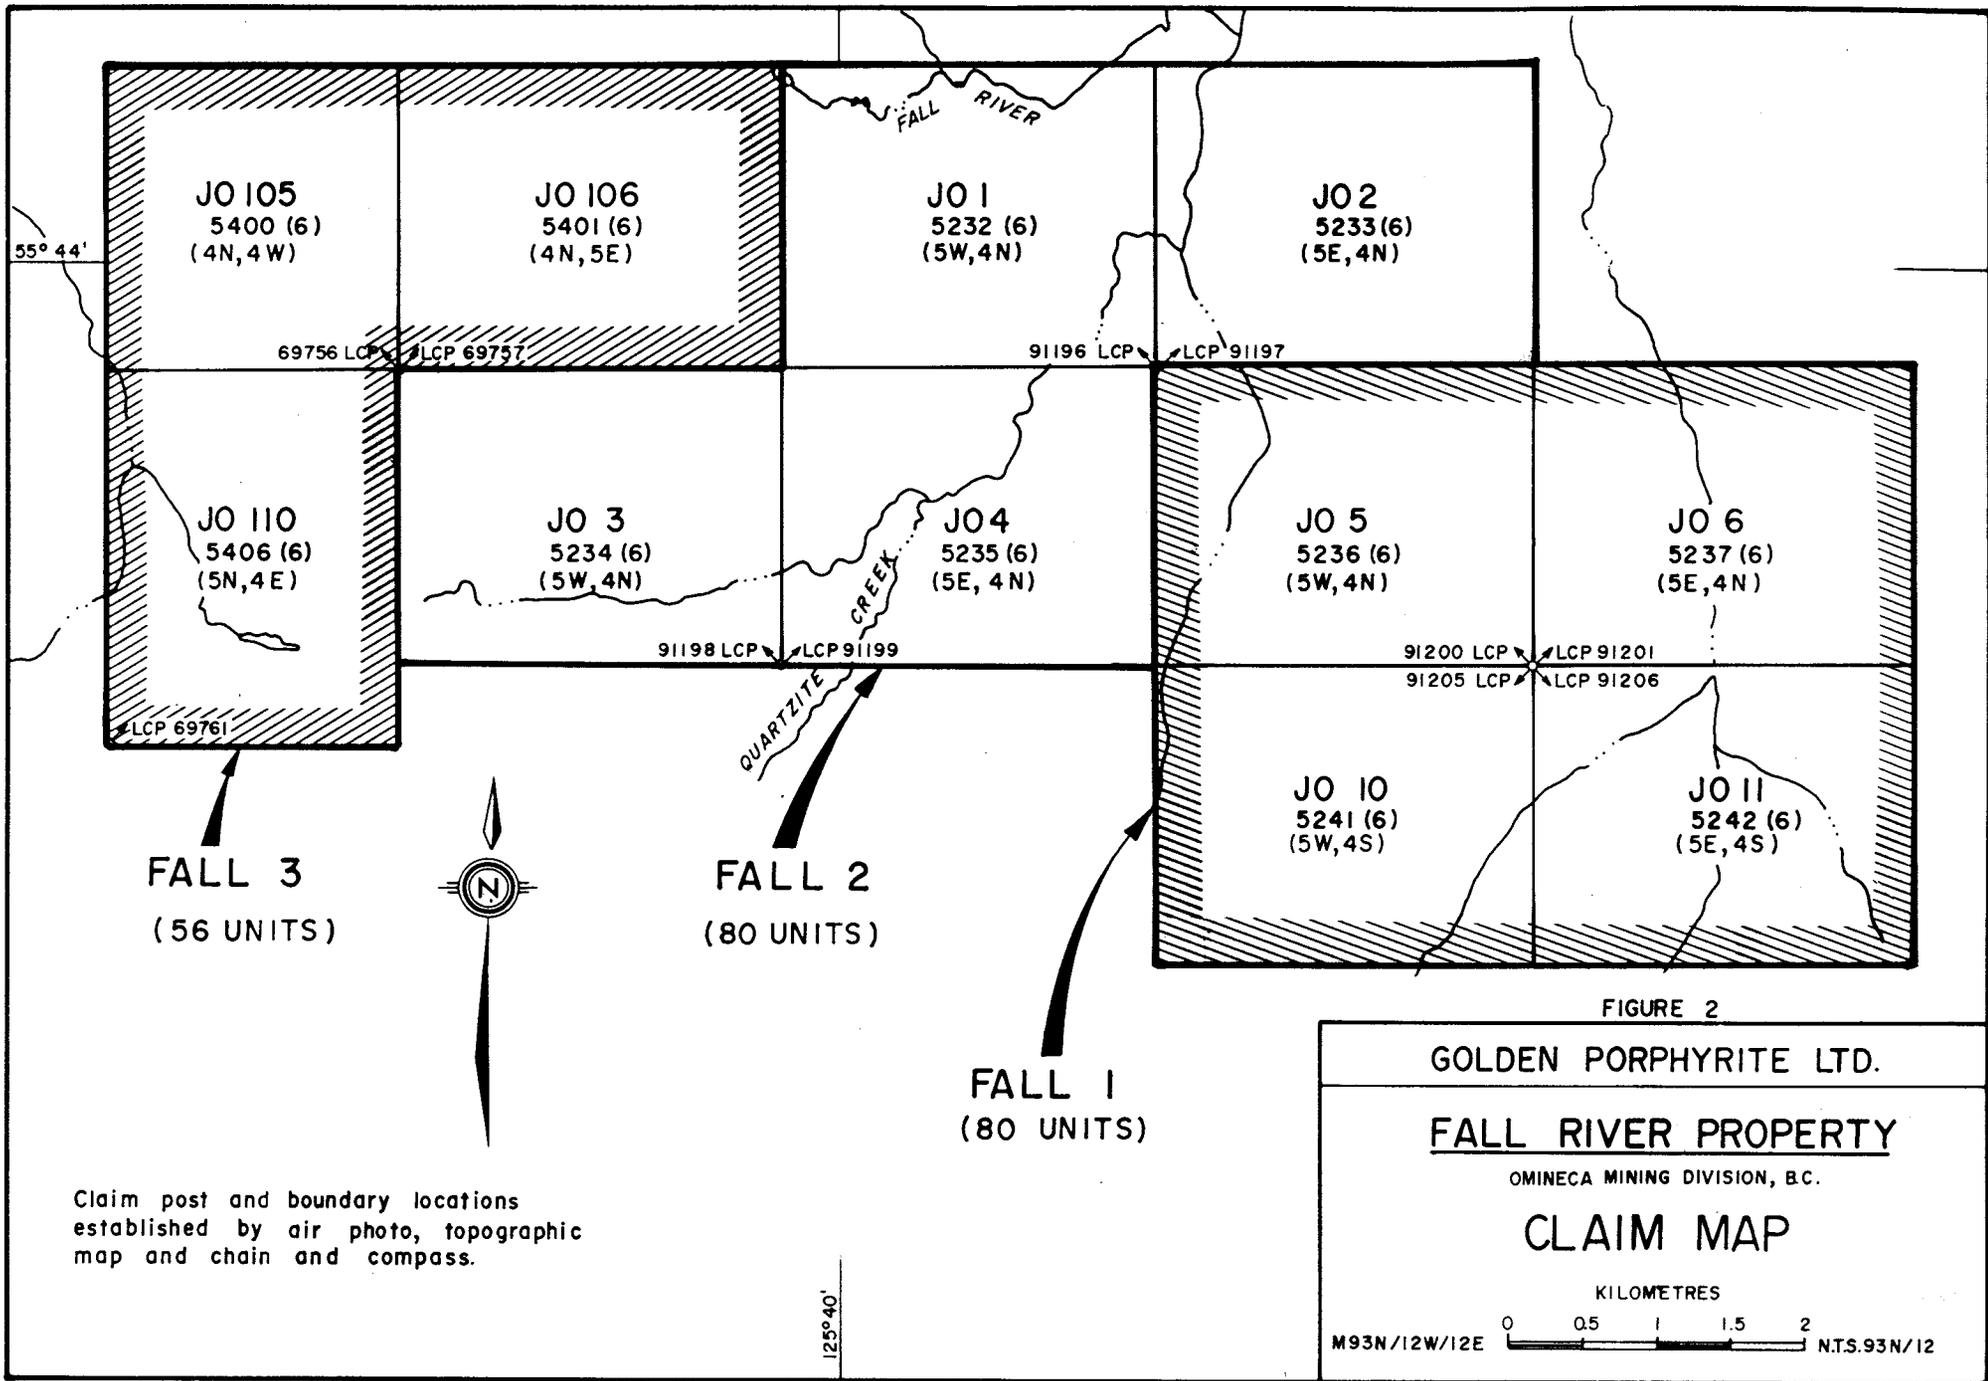

The work was performed by Golden Porphyrite personnel supervised by Mr. H. Macfarlane and directed by Mr. F.M. Smith, P.Eng. The area was geologically mapped and prospected over an area of approximately 54 km². A total of 11 geochemical rock chip and 222 soil samples were collected.

For grouping purposes the Fall River property will be divided into three groups, Fall 1, Fall 2 and Fall 3, (fig. 2).

GEOLOGICAL SURVEY

Regional Geology

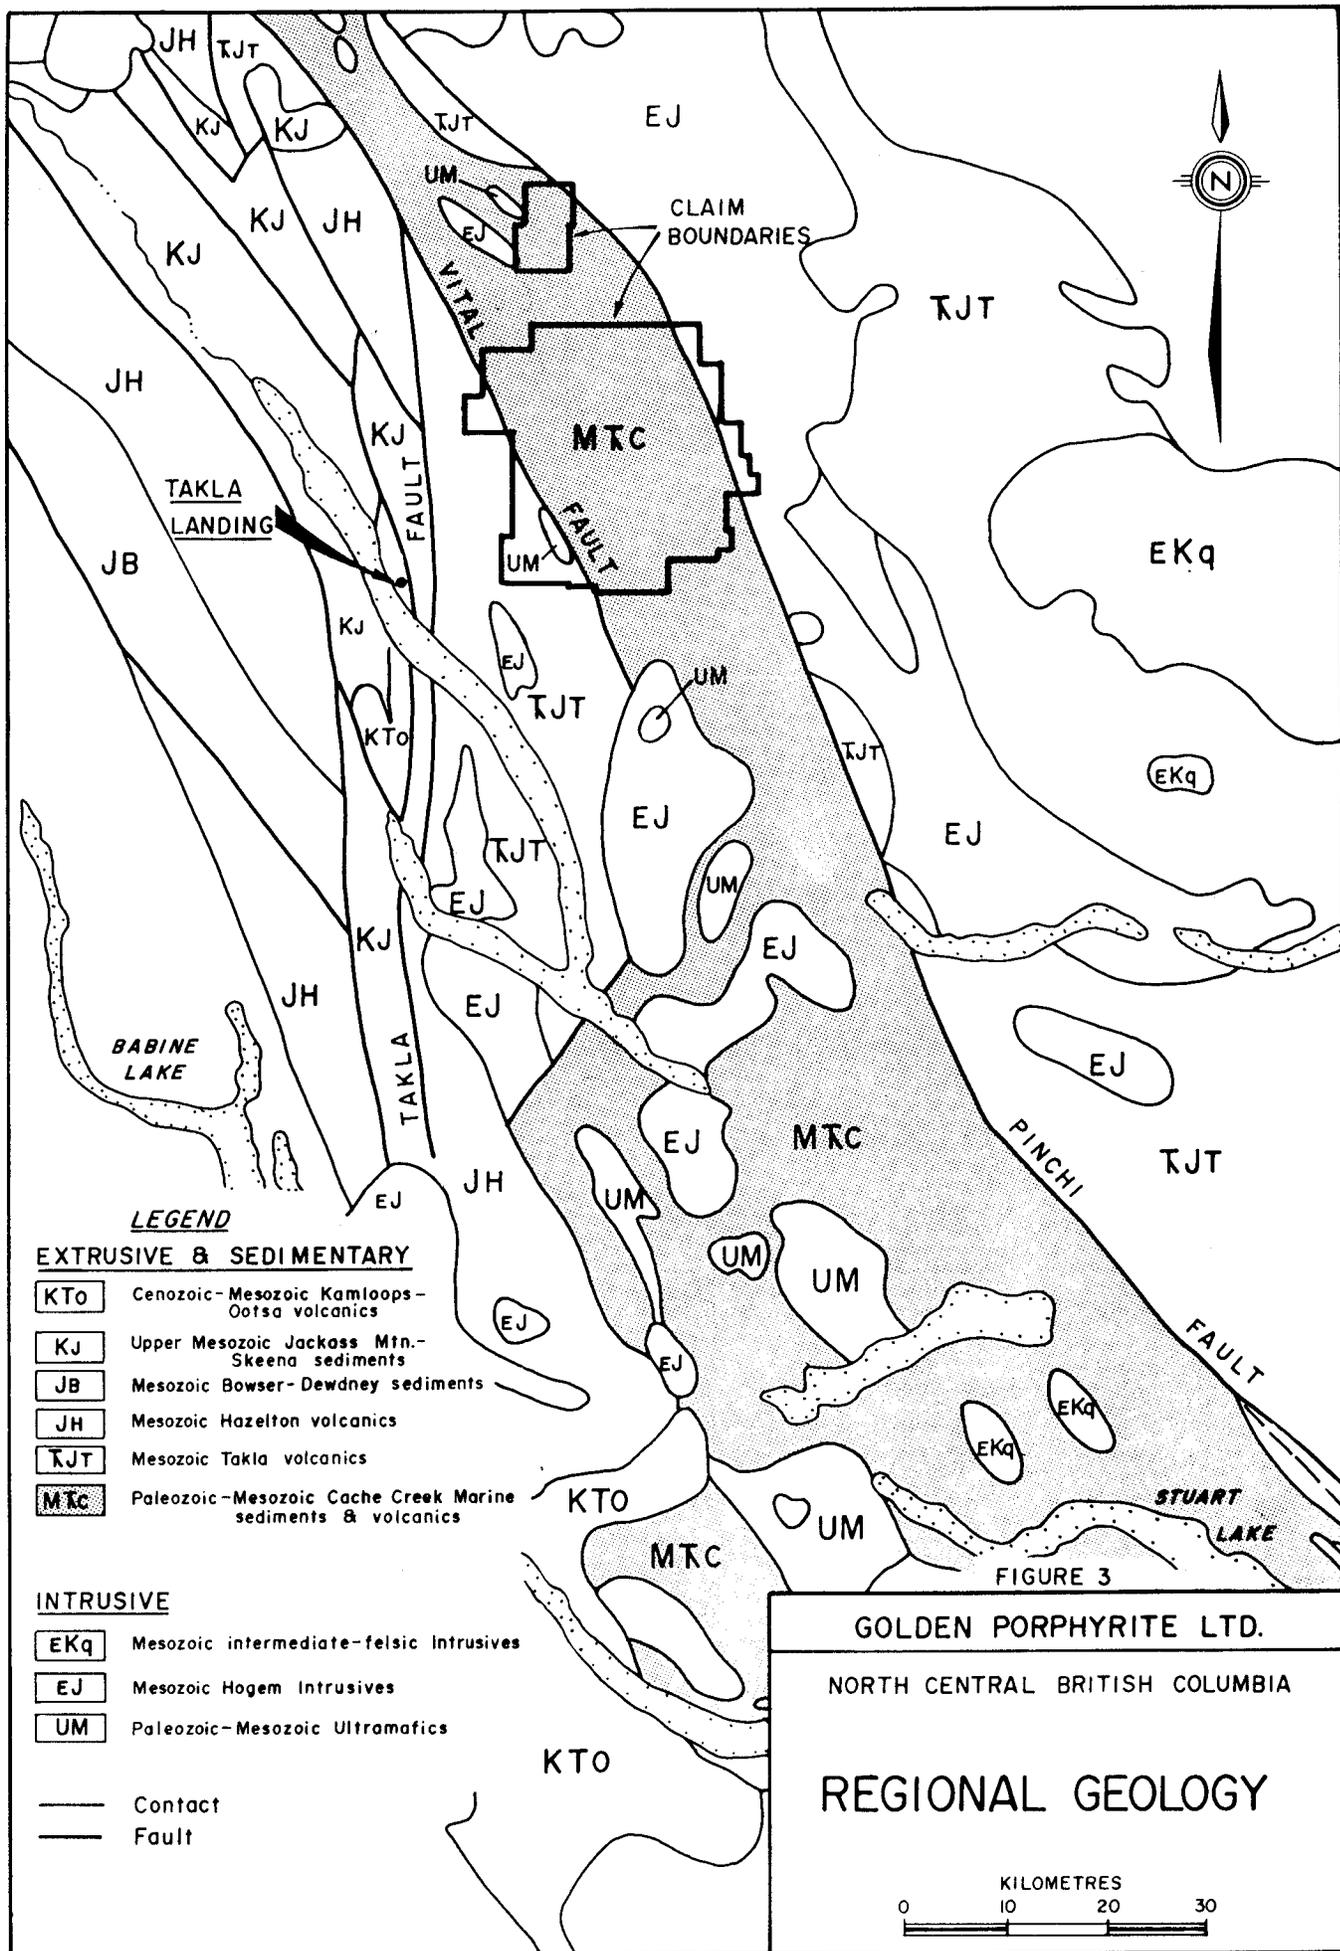

The property is situated in the Omineca Tectonic Belt of the Canadian Cordillera. It lies between the Vital and Pinchi Faults and is underlain by the Permo-Triassic Cache Creek Group. This group was first mapped in this area in the early 1940's by the Geological Survey of Canada and later in 1974. The Cache Creek Group consists of highly deformed phyllite, chert and argillite with local greywacke and contains discontinuous bodies of carbonate and metavolcanic rocks. The Cache Creek Group is separated from the Jurassic Hogem Batholith by the Pinchi Fault, (fig. 3).

Local Geology

The Fall River property was geologically mapped and prospected at a scale of 1:20,000 predominantly along ridge crests and slopes, over an area of 54 km².

Units of the Cache Creek Group present within this property are: cherty argillite, limestone, phyllite, tuff and intermediate to felsic igneous rocks, (fig. 4).

The cherty argillite member is grey-black and is frequently interlaminated with chert on a 1-10 mm scale. This unit displays well developed foliation parallel or sub-parallel to the original bedding. The limestone occurs as thinly bedded to massive units 200-300 m wide in surface exposure and is grey-black in colour, recrystallized, dolomitic in part and probably micritic in origin.

The phyllite units are green-grey to black in colour and frequently display foliation parallel, or at an acute angle to the bedding. Tuff occurs as green to black units fine to medium grained, vesicular, vuggy and probably andesitic in origin. Foliation is well developed in part and is parallel or sub-parallel to the original bedding where seen.

The intermediate to felsic igneous rocks are grey in colour and weather orange brown. They have a grey fine grained matrix supporting euhedral phenocrysts of brown plagioclase and glassy quartz ± accessory pyrite. These are thought to occur as small often isolated lenses 5 - 10 m thick, 30 - 50 m wide with an unknown length, or as closely spaced 'en echelon' lenses.

A stratigraphic sequence for the Cache Creek Group present on this Property has yet to be determined.

Most of the Cache Creek Group units strike west to northwest with a predominantly shallow northerly dip. Bedding and foliation are parallel or sub-parallel with the latter thought to have developed parallel to the north-south fold axes. Folding has resulted in the formation of antiforms and synforms. The phyllites are isoclinally folded in part and appear to have behaved incompetently with respect to the more competent limestones.

The Cache Creek Group units have undergone low grade regional metamorphism of the greenschist facies. This has resulted in the alteration of the original argillaceous sediments to phyllite. Studies by the Geological Survey have revealed that the andesitic volcanic units now contain tremolite + albite + chlorite + sphene ± epidote ± glaucophane ± stilpnomelane ± calcite ± dolomite ± white mica.

GEOCHEMICAL SURVEY

A total of 222 soil samples were collected in July and October, 1983 using the constant contour method around areas previously geologically mapped, prospected and showing signs of economic potential according to the model. Soil samples were taken from the "B" horizon at 50 m intervals along a line of constant elevation. Once extracted the soil was described and sealed in a wet-strength kraft bag for analysis. The average sample depth was approximately 20 cm. The samples taken in July, 1983, were geochemically analyzed for gold only at Min-En Labs, 705 West 15th Street, North Vancouver, B.C. The samples were dried and crushed in a ceramic plated pulverizer to - 100 mesh. A 5.0 g portion was then pretreated with a 5% HNO₃ and 70% HClO₄ mixture for one hour, digested with aqua regia, twice to dryness and taken up to 100 ml in 25% HCl. Gold was then extracted as a bromide complex into Methyl Iso Butyl Ketone and analyzed via atomic absorption with a 5 parts per billion (ppb) detection limit.

At a later date, all sample pulps were analyzed for silver by Chemex Labs, 212 Brooksbank Avenue, North Vancouver, B.C. Silver analysis required 1.0 g portions of each sample to be digested in a 20% HClO₄ - 4% HNO₃ mixture for approximately 2 hours. The digested sample was then cooled and made up to 25 ml with distilled water. The solution was then mixed and solids were allowed to settle. Silver concentration was then determined using corrected atomic absorption techniques with a detection limit of 0.1 parts per million, (ppm).

The soil samples taken in October, were analyzed by Min-En Labs, for gold as described above. The samples were also analyzed for silver at this time at Min-En Labs. A 1.0 g portion of each crushed sample was taken and digested for 6 hours in a concentrated HNO₃ and HClO₄ mixture.

After cooling the samples were diluted to a standard volume and analyzed using the CH_2H_2 -Air Flame atomic absorption method with a 0.1 parts per million (ppm) detection limit.

In the process of mapping a total of 11 1 kg rock chip samples were taken in July and October, 1983, (Appendix B). These samples were also analyzed by Min-En Labs and Chemex for gold and silver as described above.

Anomalous silver geochemical soil values were obtained from two areas on the property:

1. Four consecutive samples, with a high of 2.1 ppm Ag and a low of 1.0 ppm Ag, are present over a distance of 150 m in Jo 3 along the 1,500 m contour line.
2. Five consecutive samples, with a high of 1.6 ppm Ag and a low of 1.0 ppm Ag, are present over a distance of 200 m between Jo 3 and 4 along the 1,500 m contour line.

In addition a value of 2.3 ppm Ag is present in Jo 10.

Anomalous gold geochemical soil values of 130 and 120 ppb were obtained from two areas on the property, from Jo 3 and Jo 10.

HEAVY SEDIMENT SAMPLING

Heavy sediment samples were taken at four localities on the property and approximately 0.2 m³ of material was processed at #35 and #36 and 0.75 m³ at #16 and #17, (fig. 4). The concentrate in each case was panned down and a value on a scale from 0 to 10 was assigned dependent upon the numbers of 'colours' present. An absence of 'colours' would characterize the 0 end member and 100 to 200 'colours' the 10 end member of this scale.

Sample #17 is highly anomalous but was taken from the area of the placer workings on Quartzite Creek.

A total of 23 2-kg heavy mineral stream sediment samples were collected during October, 1983. These samples were submitted for heavy mineral analysis at Min-En Labs, and were floated in Tetrabromoethene to isolate minerals with a specific gravity greater than $2.95 \pm 0.1 \text{ g/cm}^3$. This fraction was then crushed to 100 mesh and geochemically analyzed for gold as described for rocks and soils. A ten element, Ag, As, Cu, Mn, Mo, Pd, Sr, Zn, Ba, I.C.P. analysis was then conducted. A 1.0 g sub-sample was digested for 6 hours with a concentrated HNO₃ and HClO₄ mixture. After cooling the samples were diluted to standard volume and analyzed by Jerrel Ash 900 I.C.P., inductively coupled Plasma Analyzer.

No anomalous values were obtained from these heavy mineral stream sediment samples.

CONCLUSIONS

The 1983 reconnaissance program revealed the presence of a number of areas with anomalous silver values.

A detailed program of heavy mineral sampling, soil sampling and geological traverses are required during the next field season. This program will be designed to determine whether the placer gold being recovered from Quartzite Creek is coming from sources on the Fall River property. The areas with anomalous silver values will also be investigated during the next field season.

QUALIFICATIONS

I, H.S. Macfarlane, do hereby certify:

1. That I am a geologist with business office at #403-750 West Pender Street, Vancouver, B.C. V6C 2T7 and employed by Golden Porphyrite Ltd.
2. That I am a graduate in geology of the University of London (B.Sc. Honours, 1976) and of the University of Leicester (M.Sc., 1981).
3. That I am a Member of the Institution of Mining and Metallurgy, London, and a Registered Chartered Engineer with the Engineering Council, London.
4. That I have practiced by profession as a geologist for the past seven years.
5. That I personally supervised the field work and assessed the data resulting from the geological and geochemical surveys on the Jo 1-6, 10-11, 105-106 and 110 mineral claims.

H.S. Macfarlane, M.Sc.

Dated at Vancouver, British Columbia, this 18th day of June, 1984.

Rock Chip Sample Descriptions

B 211 Intermediate to felsic igneous float
B 212 Intermediate to felsic igneous float
B 214 Intermediate to felsic igneous rock
B 215 intermediate to felsic igneous float with minor sulphides
B 216 Volcanoconglomerate
E 363 Quart veining in andesite
H 16 Intermediate to felsic igneous float
R 11 Intermediate to felsic igneous float
R 14 Intermediate to felsic igneous float
R 15 Andesite tuff with pyrite and chalcopyrite
V 544 Pyrite and chalcopyrite in argillite

TOTAL: 11 rock samples
23 stream samples
222 soil samples

STRATIGRAPHY

- CACHE CREEK GROUP
PERMO-TRIASSIC
- Cherty Argillite, locally phyllitic
 - Limestone, micritic, in part recrystallized
 - Intermediate-felsic igneous rocks
 - Intermediate-felsic igneous float
 - Phyllite, locally cherty or quartz rich
 - Tuff, locally intercalated with limestone or phyllite

SYMBOLS

- Bedding; with amount of dip
- Bedding; vertical
- Foliation; with amount of dip
- Foliation; vertical
- Syncline
- Anticline
- Dyke; with amount of dip
- Dyke; vertical
- Geological Contact - very uncertain
- Geological Contact - uncertain
- Geological Contact - observed
- Outcrop
