DRILL LOGS FOR HOLES 180-125 and 180-127	11
--	----

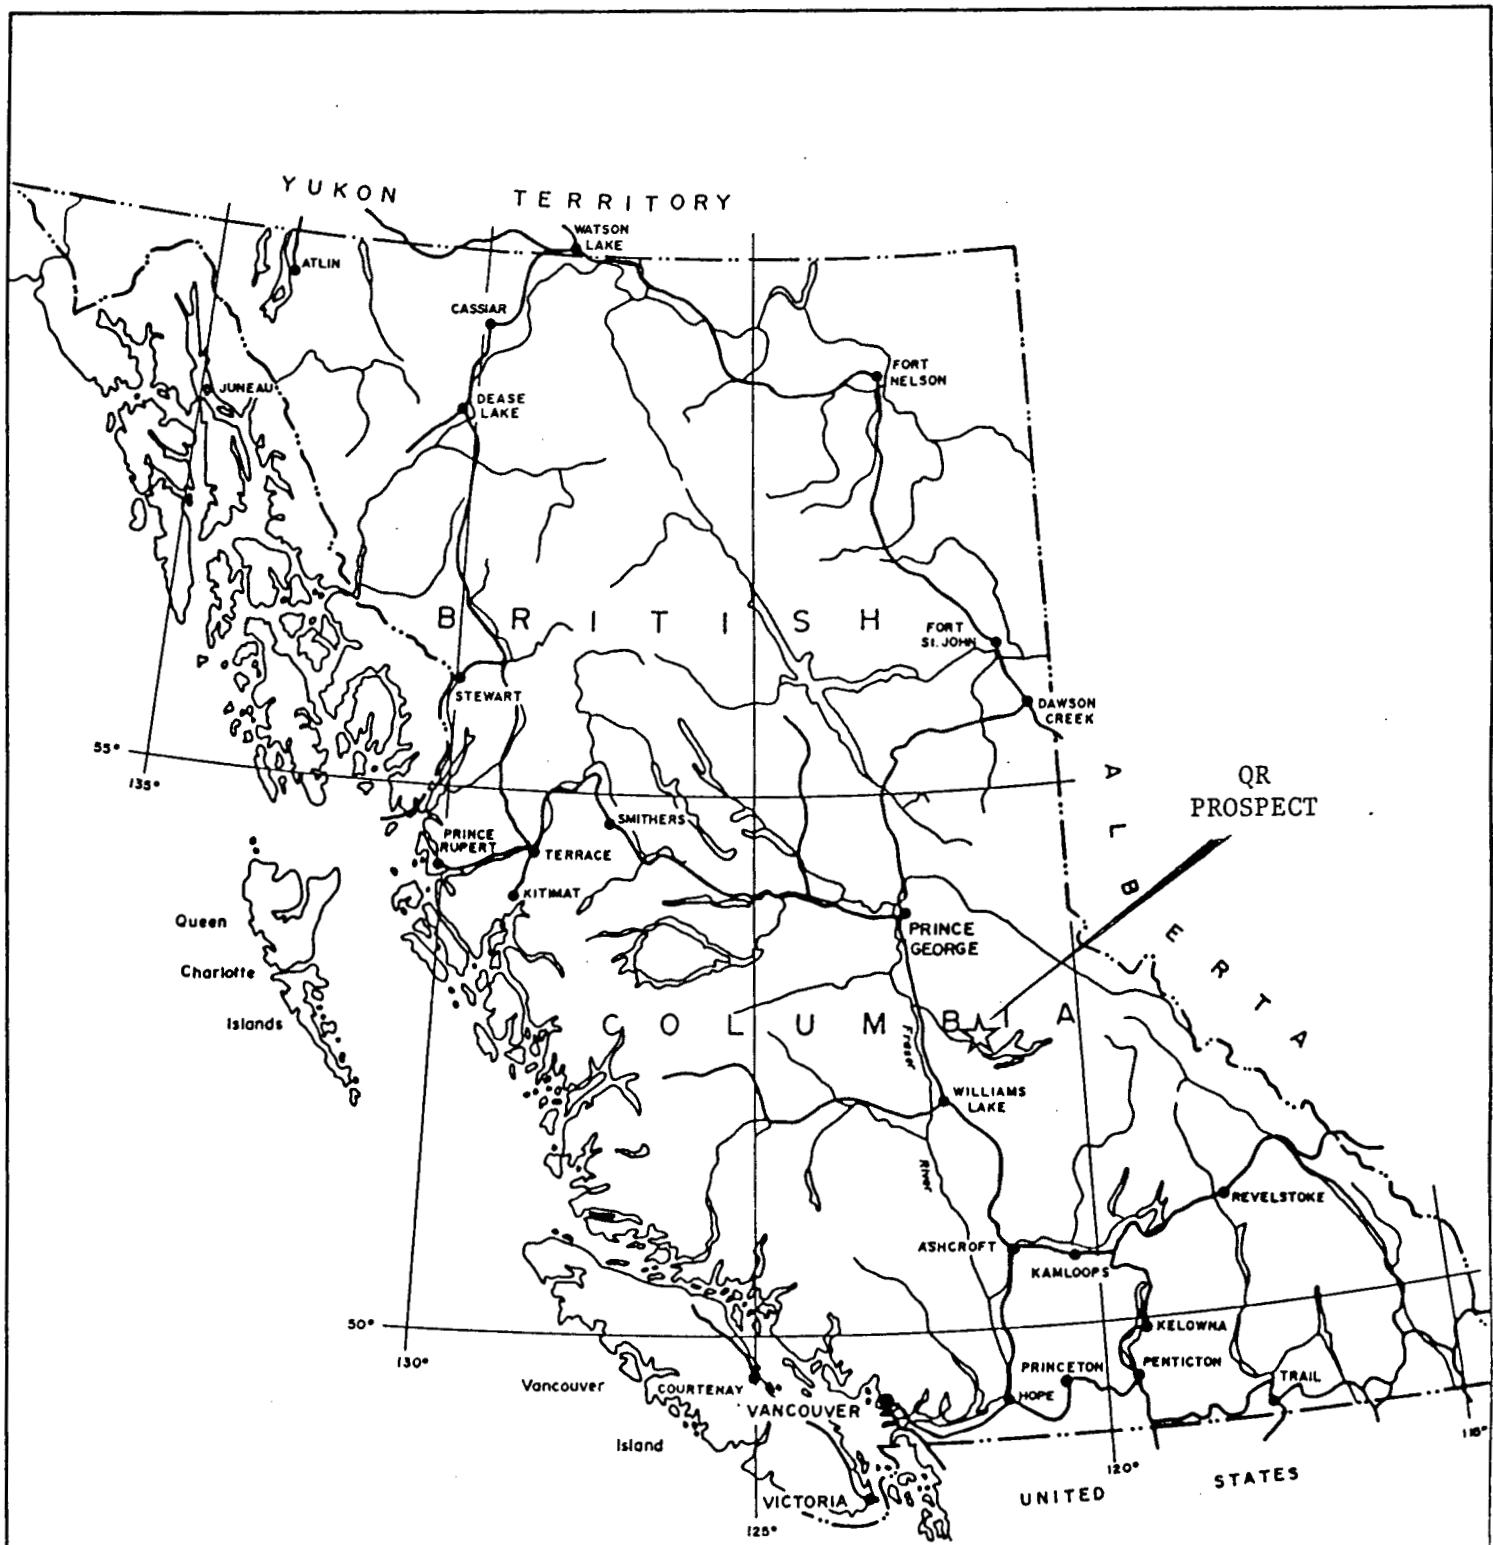

INTRODUCTION

Results of diamond drilling work done on the QR claims between November 17 and December 11, 1983 are given in this report. Drill logs and assays for holes 180-125 and 180-127 are appended. The drilling program was designed for evaluate a gold prospect originally staked in 1975 and explored by a series of drilling programs in 1976, 1977, 1978, 1980, 1981 and 1982. A total of 149 diamond drill holes comprising 27,120 metres has been drilled to date.

LOCATION, ACCESS AND TOPOGRAPHY

The Quesnel River property is situated 58 kilometres southeast of Quesnel and 10 kilometres west of Quesnel Forks (Figure 1). Access to the site is by a series of gravel-surfaced roads from Quesnel via Sardine Flats to Maud Lake (45 kilometres) and a rough, four-wheel drive access trail from Maud Lake to the Quesnel River camp, a distance of 12 kilometres (Figure 2).

Local terrain consists of rolling hill country of the interior plateau region. Deeply incised valleys of Quesnel River and Maud Creek are situated near the south and east boundaries of the QR claim block respectively. Relief from the Quesnel River to summit areas northwest of the deposit is 500 metres. The deposit, at an elevation of 1000 metres, is situated in a low depression between the Quesnel River to the south and a swampy, muskeg-filled valley that drains northerly to Maud Creek.

GEOLOGY

The Quesnel River property covers a dioritic stock and mineralized volcanic strata on the north side of the Quesnel River. The property is situated 15 kilometres north of the Cariboo Bell copper-gold prospect situated on Polley Mountain. The Quesnel River prospect is associated with a small alkalic intrusion consisting of diorite, monzdiorite and monzonite that intrudes a thick succession of augite basalt, trachybasalt, felsic breccia, and volcanic wackes and sediments. Bedrock exposures on the property are confined to rocky summits and on steep slopes of the Quesnel River valley. The remainder of the area consists of gentle slopes where bedrock is covered by several metres of till.

Dark grey basaltic flows and layers of unstratified autobreccia form rocky summits and ridges in the north half of the property. Poorly bedded volcanic wackes and sedimentary grits outcrop at lower elevations to the south and form steep limonite-stained bluffs above the Quesnel River near the north boundary of the QR 4 claim. The bluffs comprise a conspicuous gossan zone visible for many miles to the south. The sediments strike easterly, dip 60 degrees south, and overlie the basaltic rocks exposed to the north.

Augite diorite and biotite monzodiorite form a composite stock exposed on steep bluffs and talus slopes north of the Quesnel River. The stock is exposed along the valley side for 1000 metres. Outcrops of diorite extend southerly almost to the Quesnel River but the stock is apparently covered by thick accumulations of glacial clays south of the river. The east and north part of the stock is highly fractured and altered to K-feldspar veinlets and irregular patches of epidote. Pyrite is abundant and forms disseminated grains and films and fractures.

The deposit occurs in pyritic, carbonate-epidote-chlorite rocks bounded to the north by carbonate-rich basaltic rocks and to the south by pyritic siltstones. The deposit is terminated to the east by a west-dipping fault and to the west, the deposit merges downward into barren basaltic rocks. The best grade material lies in pyritic rocks close to the north-dipping contact with carbonate-rich basaltic rocks. The mineralized zone comprises two types - disseminated and locally massive pyritic material in altered tuffs and lapillistones and stringer type pyrite-carbonate-epidote veinlets in massive basalts.

1983 FALL DRILL PROGRAM

The fall program comprised twenty-two new holes (180-106 to 180-127), a total of 2,844.5 metres, completed between November 17 and December 11, 1983. Drilling was done by J.T. Thomas of Smithers, B.C. The core was logged, recoveries calculated, split and sampled in 1-metre lengths. Samples were assayed for gold, silver and copper by Acme Analytical Laboratories Limited. Drill hole data are given in Table I. Core is stored at 1252 Jade Road, Quesnel, B.C.

DRILL RESULTS

180-125

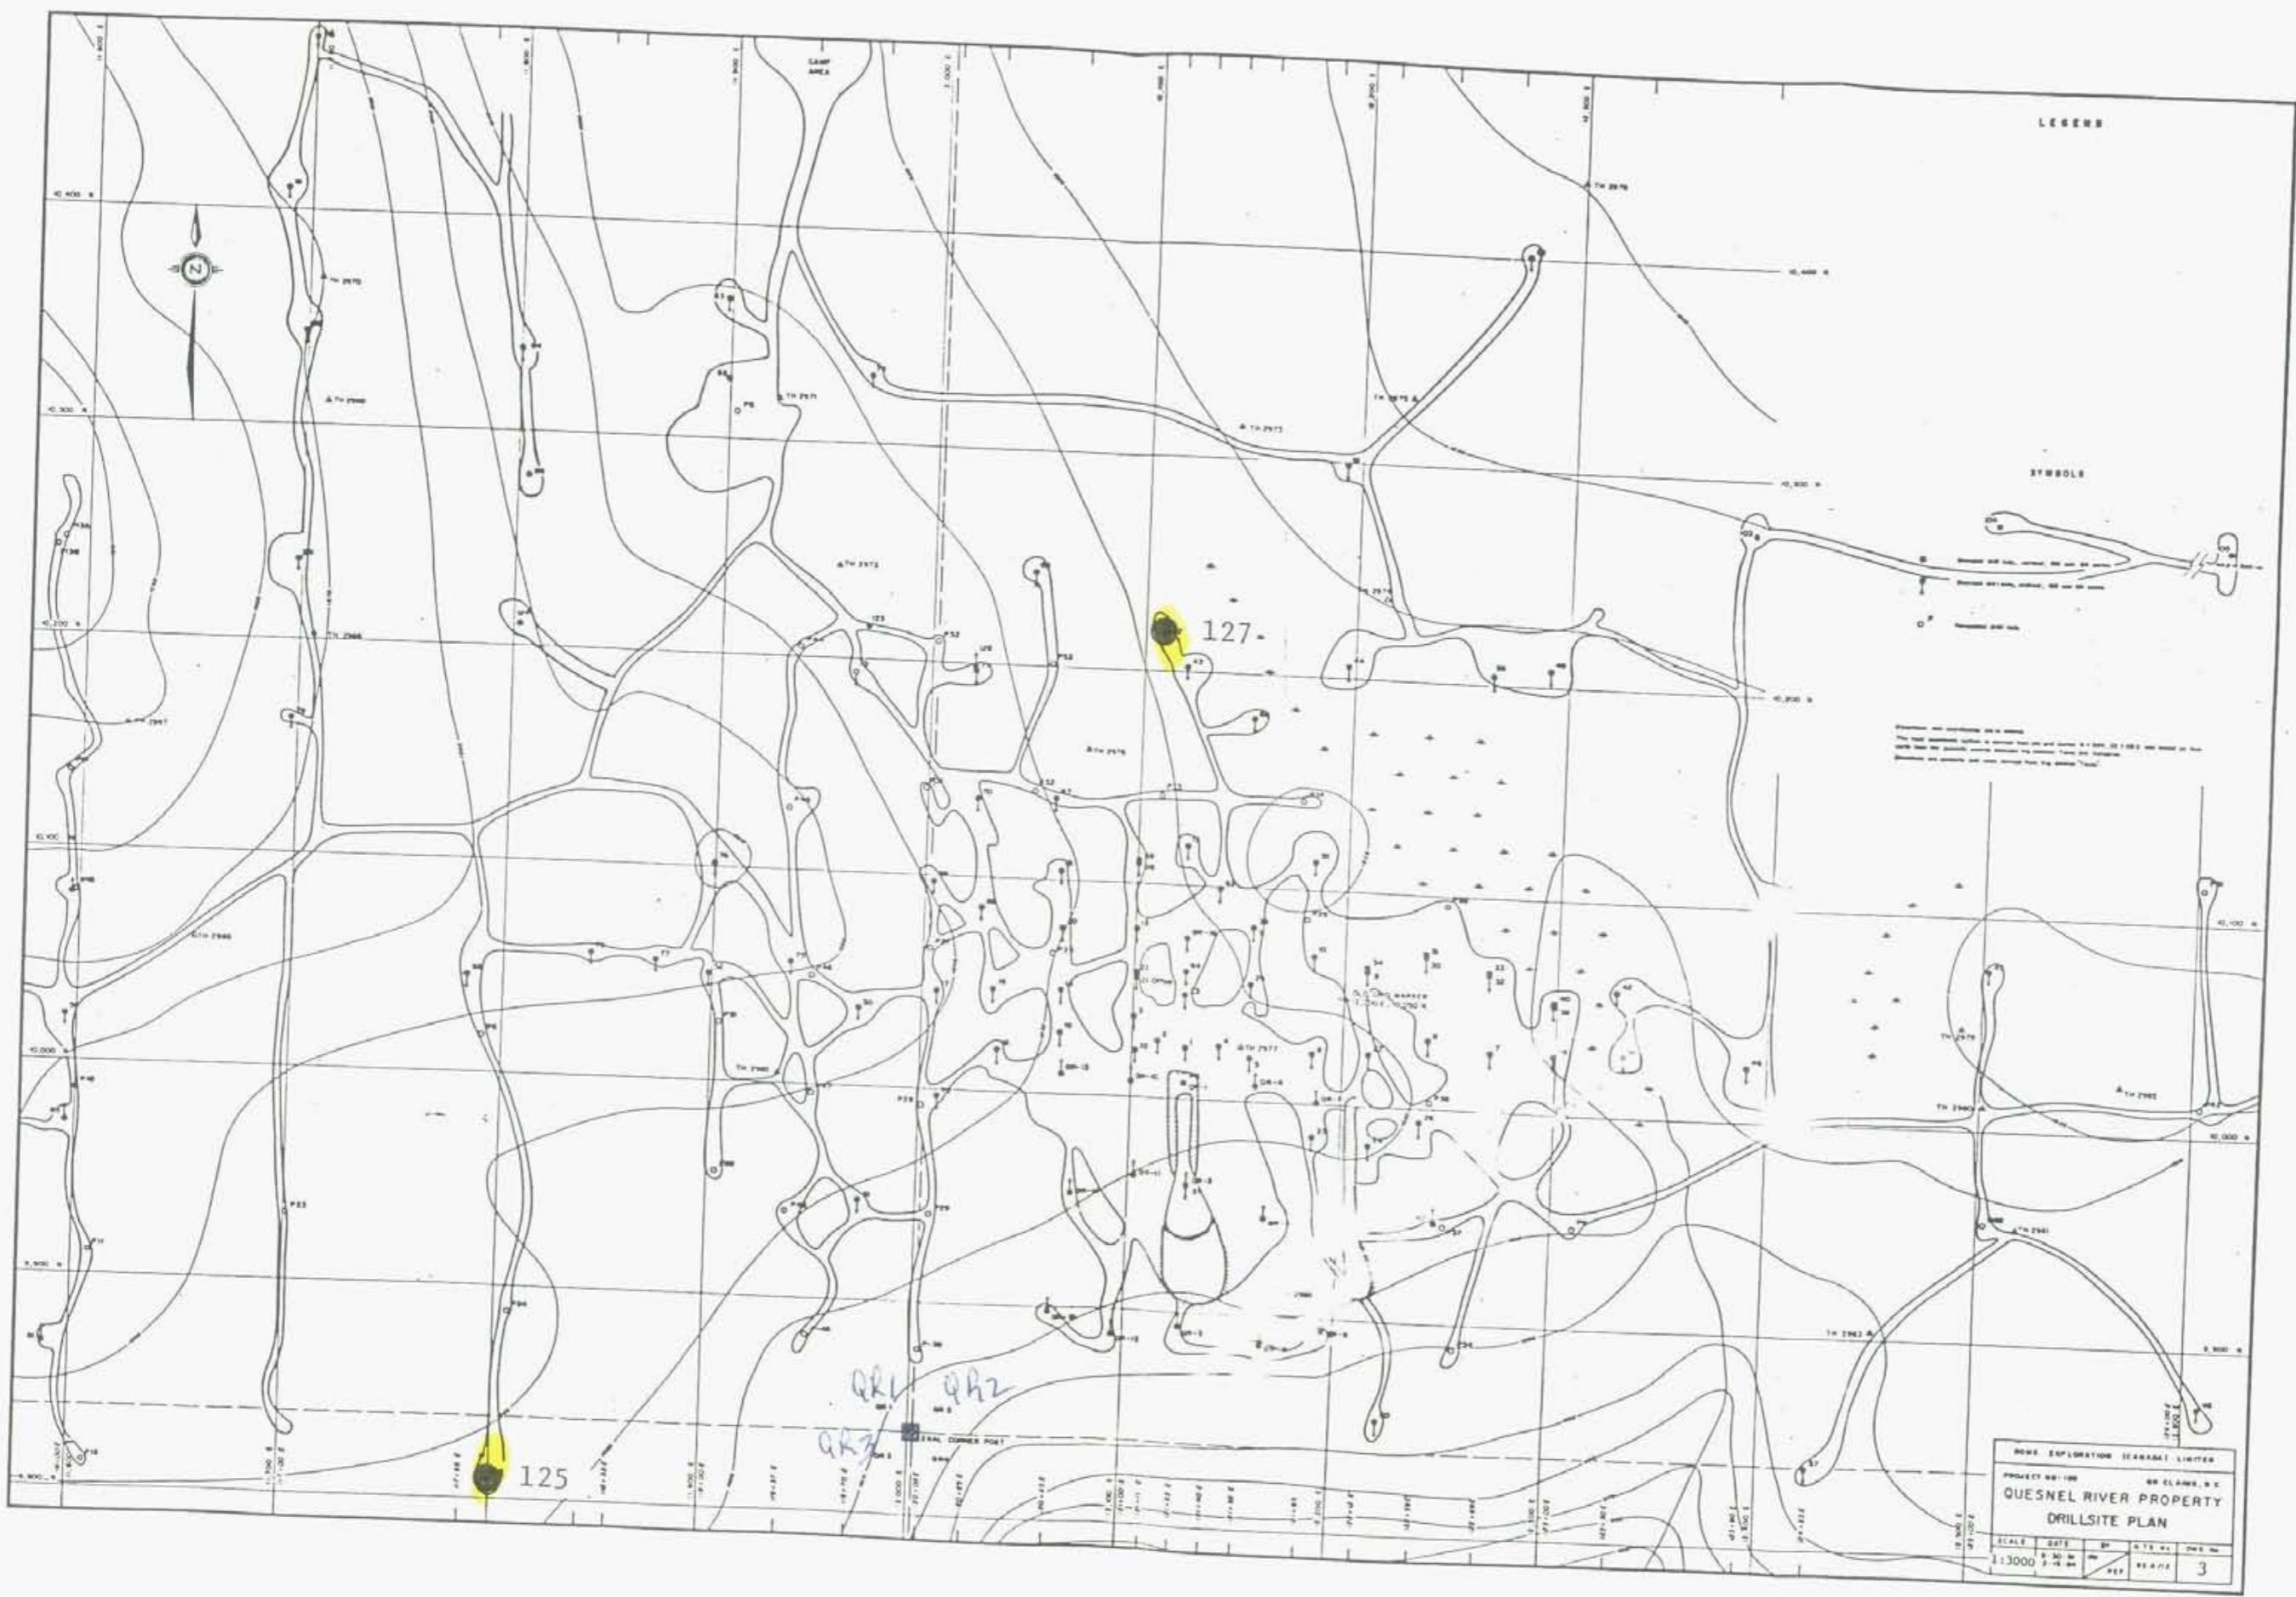

Hole 180-125 was collared 400 metres south of hole 180-124 and drilled vertically to a depth of 298.7 metres.

0.0m	to	12.2m:	Overburden
12.2m	to	144.4m:	Hornfels siltstones cut by numerous hornblende porphyry dykes
144.4m	to	283.1m:	Basalt cut by felsic or mafic dykes
283.1m	to	286.5m:	Chloritic fault gouge
286.5m	to	298.7m:	Diorite

180-127

Hole 180-127 was collared 110 metres east of holes 180-126 and drilled vertically to a depth of 154.5 metres.

0.0m	to	12.2m:	Overburden
12.2m	to	34.3m:	Calcareous basalt
34.3m	to	114.6m:	Hornblende feldspar porphyry dyke
114.6m	to	154.5m:	Calcite-cemented lapilli tuff cut by mafic dykes

CERTIFICATE

I, Robert S. Cameron, of the city of Vancouver, British Columbia, do hereby certify that:

1. I graduated from Carleton University in 1981 with a Bachelor of Science degree in geology.
2. I have been practicing my profession as a geologist since 1981.
3. I work on the QR claims on November 1, 1983 to February 1, 1984.

Dated at Vancouver, B.C. this 4th day of August, 1984.

Robert Cameron
