SUMMARY

The CAMBAC 1 and 2 claims cover the southeast extension of the phyllite member of the Triassic Nicola Group which hosts stratabound gold mineralization on the Fraser gold property.

A total of 10 man days were spent prospecting, mapping and sampling the claims. A total of nineteen rock chip samples were collected and analysed for gold and arsenic. Thirty-six silt samples and eighty-one soil samples were analysed for gold, arsenic, copper and zinc. Samples anomalous for Zn and Cu were run for silver.

The only mineralization observed was limonite-stained quartz ± calcite sweats filling dilatant zones in the cross-folded phyllitic rocks. The contact aureole at the Raft Batholith has metamorphosed the pelitic rocks to spotted phyllites, andalusite schist and biotite and calc-silicate hornfels.

The interbedded phyllite-iron carbonate unit which hosts the Fraser gold mineralization was not found on the CAMBAC claims. Sparse outcrop makes determination of structure difficult. Formations appear to dip to the north east.

The relatively intense silt and soil sampling conducted along the road in the higher northern part of the property failed to indicate significant values for the elements determined.

In the southeast corner of the property several soil samples returned values from 160 to 800 ppm zinc and two samples gave values of 125 and 290 ppm copper. These values appear to occur in the more highly altered rocks above the volcanoclastic grit.

No gold values were obtained and no appreciable silver values were obtained from those samples anomalous in copper and zinc.

Geochemically anomalous values in zinc and copper are restricted to the southeast corner of the property. It is possible more detailed work here would reveal additional outcrop and further soil sampling on a tape and compass grid should be carried out to define the anomalous area. If open ground exists to the east and south further staking may be warranted depending on results of this additional work.

INTRODUCTION

The CAMBAC 1 and 2 claims were staked in November 1983 to cover a geologically favourable target for gold mineralization. The claims are at the southeastern end of the Cariboo-Quesnel Gold Belt, currently the focus of considerable gold exploration activity. The stratigraphy covered by the property is the lateral equivalent of the sedimentary sequence which reportedly hosts low grade stratabound gold mineralization on the Frasergold prospect. If this mineralization is of syngenetic origin, then these sedimentary rocks form a favourable exploration target of regional extent. (Saleken and Simpson, 1984).

To assess the validity of this geological model on the CAMBAC claims, a program consisting of prospecting, geological mapping and rock, silt and soil sampling was carried out in June 1984.

LOCATION, ACCESS and TOPOGRAPHY

The CAMBAC claims are located 25 km northwest of Clearwater B.C. as shown in Figure 1. The claims are in Kamloops Mining Division.

The claims are readily accessible by truck from Clearwater. A campsite on Coldscaur Lake at km 29 of the Mann Creek Forestry Main was used and several branch roads provide direct access to the property.

The topography of the property is a moderate southwesterly facing slope from 3800 to 5400 feet elevation. The southern claim boundary crosses flat-lying swampy ground.

Approximately half of the claim area has been clear cut in the past and is in the early stages of forest regeneration. The uncut blocks are forested with mature lodgepole pine and fir.

Most of the property is blanketed with glacial till and alluvium. Outcrop exposure is very poor despite the numerous road cuts.

The field work in mid-June was hampered by persistent snow above 5000 feet elevation. Creek levels were high due to meltwater and several areas of the logging roads were flooded.

FIGURE 2

REGIONAL GEOLOGY

The regional geologic setting of the CAMBAC claims is shown in Figure 3 taken from GSC Map 1278A (Campbell and Tipper, 1971)

The southern margin of the Cretaceous Raft Batholith (20) lies near the northern claim boundary. The flat-lying ground in the southern claim area consists of valley-filling flood basalts (25) of Tertiary age. The sedimentary rocks exposed in the claim area had been tentatively mapped as volcaniclastic rocks of Jurassic age (15?). The present work indicates the lithology is much more similar to the black shales and phyllites of the Triassic Nicola group. (10). The belt of Nicola rock mapped south of the CAMBAC claims appears to be continuous with the Nicola rocks to the north, near Mahood Lake. This belt of sedimentary rocks continues northwest and has been deformed by the Crooked Lake synclinal structure in the vicinity of the Frasergold property.

TABLE I

LITHOLOGY

UNIT

- Vb Tertiary valley basalt. Tan-weathering, dark grey vesicular basalt, basaltic andesite. Fine feldspar phenocrysts. Does not outcrop but abundant float in flat-lying valley floor.
- Ig Intrusive rocks. On CAMBAC claims represented only by one small dyke of porphyritic quartz monzonite. Abundant glacial float of biotite ± hornblende quartz monzonite, granodiorite, muscovite granite, aplite and pegmatite from Raft Batholith to the north.
- P Metasedimentary rocks. Pelitic to argillaceous sedimentary rocks with minor graphitic and calcareous interbeds. Variably developed hornfels mineralogy. Pp - dark gray phyllite. Pg - graphitic bed. Pc - calcareous bed. Ps - "spotted" phyllite (andalusite porphyroblasts). Pb - dark purple grey fine-crystalline biotite hornfels with disseminated pyrrhotite. Pa - finely banded andalusite-quartz biotite schist. Pcs (one outcrop of) purple and green calc-silicate hornfels.
- Sv Volcaniclastic sandstone. Grey to purple (Hornfelsed) coarse volcaniclastic grit

The only intrusive rock observed, was in a 1 meter wide dyke of porphyritic quartz monzonite in an outcrop of biotite hornfels and graphitic slate near the LCP of the CAMBAC 2 claim block. The absence of metasedimentary float in with the intrusive till boulders near the northern claim line indicates the claim boundary lies at or near the intrusive contact.

The Tertiary valley basalt unit does not outcrop but is abundant in float in the flat lying area at the southern edge of the property. The northern contact of the basalt appears to be roughly coincident with the lower most east-west logging road.

STRUCTURE

The metasedimentary rocks are highly deformed. Bedding is rarely apparent in outcrop and has been affected by at least two deformations.

A prominent cleavage is developed in the phyllites and is fairly consistent in strike, varying from 100 to 130° and dipping 60 to 80° N. Near the north east corner of CAMBAC 2 the cleavage is dipping steeply to the south. Foliation in the schists parallels this cleavage. In some exposures a later cleavage is seen striking 025 to 060 and dipping 70° to the west. This cleavage crenulates the earlier cleavages and often shows small reverse offsets.

The style of the small scale folds are characteristic-ally open symmetric upright folds about the axial plane cleavage. The later cross-folding has disrupted thin competent beds within the phyllites. Where observed bedding was dipping 40° to 60° to the north but it is quite possible that one or more east-west trending folds strike across the property.

MINERALIZATION

Within the metasedimentary rocks quartz ± calcite sweats are present filling dilatant zones developed between beds of varying competency. The sweats are not abundant and range from 1 to 30 cm thickness and are generally only at most a few metres in strike length. Minor limonite after pyrite and traces of fresh pyrite are the only mineralization observed in the sweats.

The biotite hornfels unit is very rusty weathering due to oxidation of the disseminated pyrrhotite. Ferricrete-cemented overburden was observed in the vicinity of several of the biotite hornfels outcrops. The only mineralization observed in float was a boulder of coarse crystalline quartz monzonite with molybdenite rosettes on a dry fracture. Minor calc-silicate hornfels and rare poorly developed biotite-diopside skarn boulders were also seen but appear to be barren.

GEOCHEMISTRY

FIELD PROCEDURE

Nineteen rock chip samples were collected for analysis for gold and arsenic. Outcrops sampled included the various rock types and several samples were collected from the limonite stained quartz ± calcite sweets.

Thirty-six silt samples were collected from the fast flowing streams which were at high levels due to meltwater.

Two lines of soil samples, totalling seventy-four samples were collected. One line follows the eastern most claim line which is approximately perpendicular to the strike of the prominent cleavage. Samples were collected at 100 metre intervals from the B horizon. A second line of soil follows the upper logging road and is a contour soil line. Samples were collected at 50 metre intervals from the B horizon where exposed at the top of the road cut. Seven additional soil samples were collected from rusty zones on two small graphitic shears.

Sample Data sheets and analytical procedures are included in Appendix I and II.

GEOCHEMICAL RESULTS

(1) Rock Geochemistry

Rocks were analysed only for arsenic and gold. No gold values were obtained. Arsenic values range from 1 to 23 ppm and cannot be considered anomalous.

(2) Silt Geochemistry

Silt values range from 5 to 53 ppm copper which cannot be considered anomalous. Values for zinc range from 24 to 253 ppm. The distribution curves, Figure 4, suggest a very small (2 sample) anomalous population with values of 225 to 253 ppm. These values occur in the east central portion of CAMBAC 2.

Arsenic values range from 2 to 15 ppm and, except that the 15 ppm value coincides with the single 20 ppb gold value, cannot be considered anomalous.

A single value of 20 ppb gold was obtained in silts.

It may be significant that the few relatively high zinc values obtained occur in the east portion of the property. Zinc, being the most soluble of the elements analysed, may indicate mineralization otherwise masked by the extensive glacial cover.

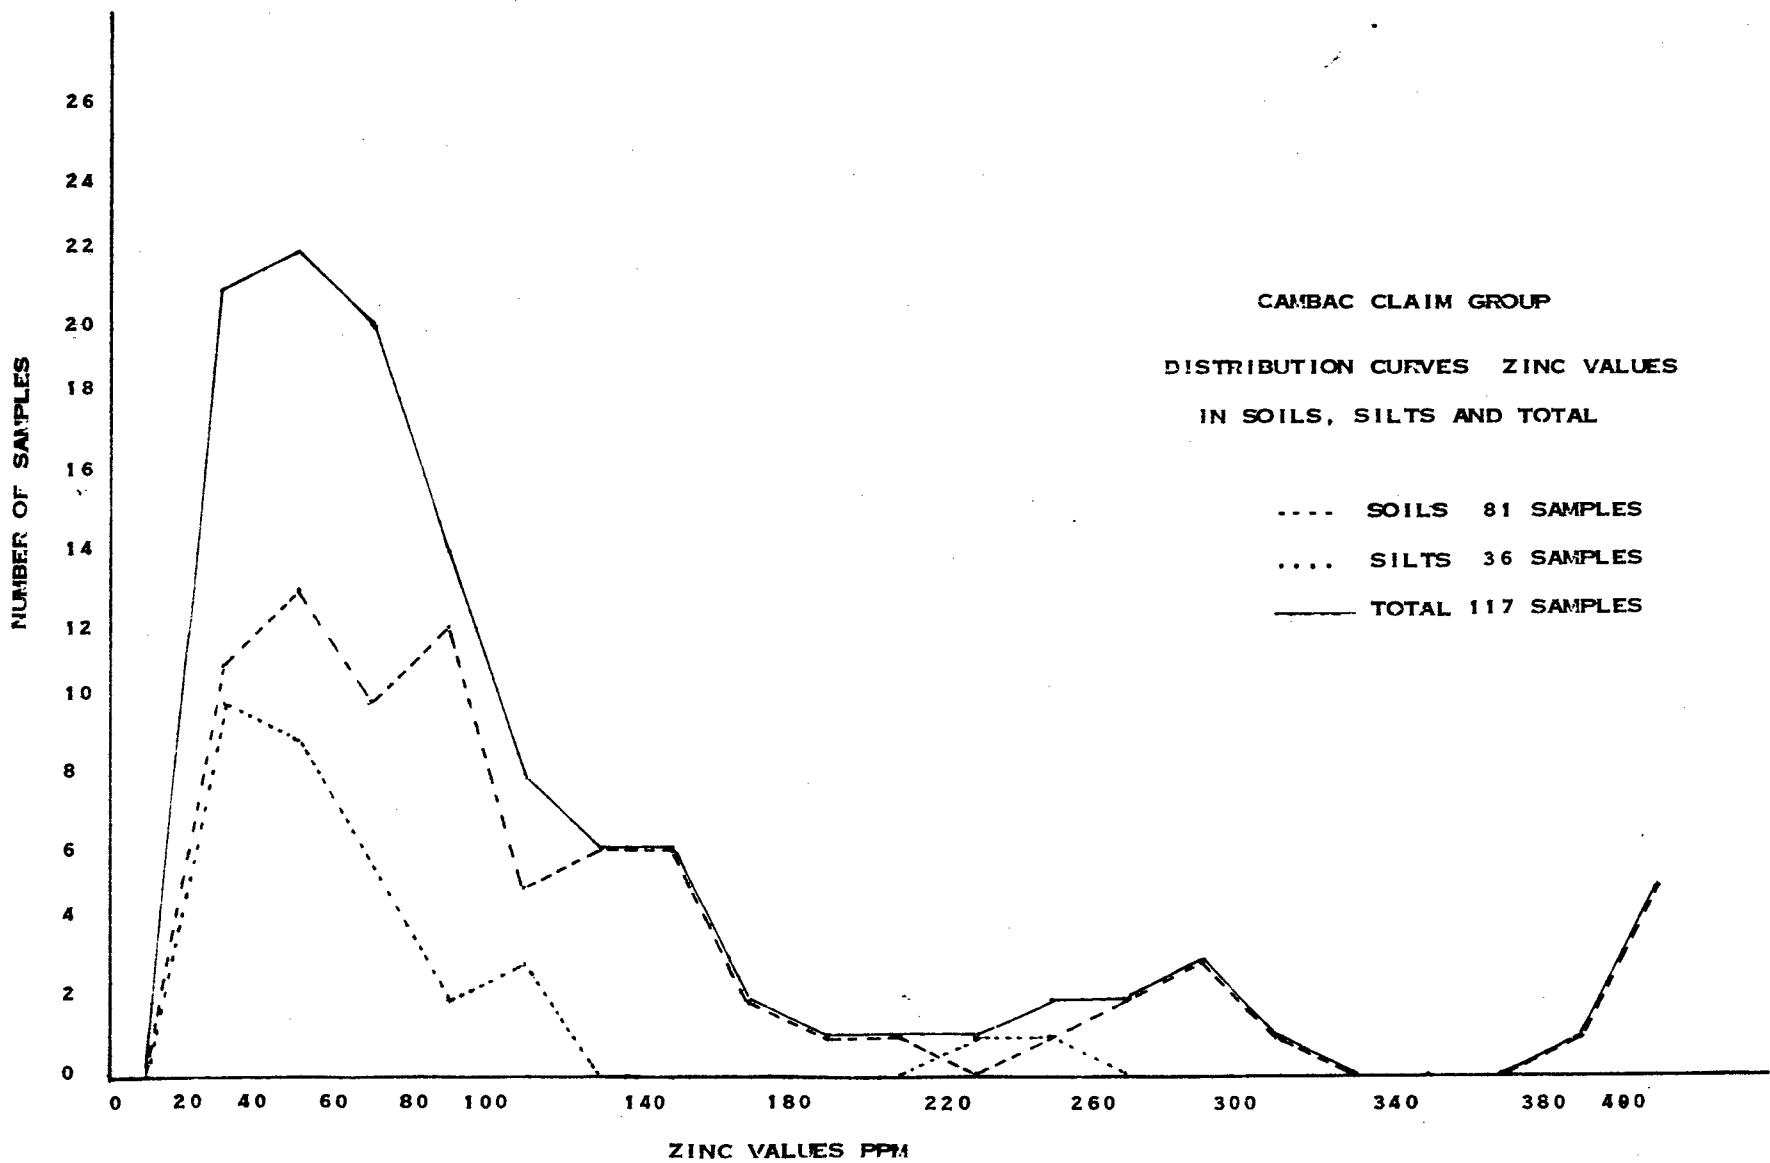

FIGURE 4

(3) Soil Geochemistry

Soil values range from 4 to 290 ppm copper. The two highest values, 125 and 290 ppm, as well as four values ranging from 40 to 72 ppm occur in the eastern portion of the property.

Values for zinc range from 20 to 800 ppm. The distribution curve, Figure 4, suggests two families of anomalous values in the ranges 220 to 320 ppm and >400 ppm. These higher values all occur in the eastern portion of the property.

Arsenic values in soil samples range from 1 to 48 ppm. Although none of these are definitely anomalous it may be significant that all but one of those values of 10 ppm or greater (15 out of 81 samples) occur in the eastern portion of the property.

Twelve soil samples returned 10 ppb gold and one returned 20 ppb gold. These cannot be termed anomalous and there is no apparent concentration of these values in any one portion of the property.

Silver was analysed in 41 samples which were anomalous for zinc and copper. Silver values range from 0.1 to 1.9 ppm and cannot be considered anomalous.

DISCUSSION

DISCUSSION

Although the CAMBAC property is a technical success in that it does cover the favourable phyllite member of the Nicola Group it does not appear to host any significant gold mineralization. No iron carbonate bearing phyllites or sweets were found in outcrop or float. The quartz-calcite sweets appear to be barren and of little consequence.

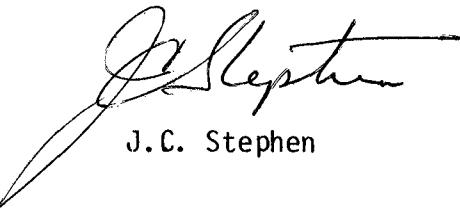

Widespread glacial overburden makes exploration difficult but concentration of moderate zinc, low to moderate copper and minor arsenic geochemical values in the eastern portion of the property suggests possible mineralization above the volcanogenic grit horizon. It is not clear whether these values are associated with thermal alteration from the Raft batholith since the highest values are in the southeast part of the property apparently some distance from the batholith. No evidence of Tertiary epithermal type alteration has been detected but these highest values are in the area close to Tertiary basalts.

RECOMMENDATIONS

No precious metals values have been obtained on the CAMBAC claims and no exploration program is immediately recommended.

Geochemical values for zinc with indications of copper and low to moderate arsenic values occur in the east portion of the property. This area would warrant some further investigation in an effort to find the source of these values. Some detailed prospecting with additional soil sampling should be carried out at a convenient time.

Respectfully submitted,
J.C. Stephen Explorations Ltd.

ANALYTICAL PROCEDURES

GEOCHEMICAL PREPARATION
AND
ANALYTICAL PROCEDURES

1. Geochemical samples (soils, silts) are dried at 50°C for a period of 12 to 24 hours. The dried sample is sieved to -80 mesh fraction through a nylon and stainless steel sieve. Rock geochemical materials are crushed, dried and pulverized to -100 mesh.
2. A 1.00 gram portion of the sample is weighed into a calibrated test tube. The sample is digested using hot 70% HClO_4 and concentrated HNO_3 . Digestion time = 2 hours.
3. Sample volume is adjusted to 25 mls. using demineralized water. Sample solutions are homogenized and allowed to settle before being analyzed by atomic absorption procedures.
4. Detection limits using Techtron A.A.5 atomic absorption unit.

Copper - 1 ppm
Molybdenum - 1 ppm
Zinc - 1 ppm
*Silver - 0.2 ppm
*Lead - 1 ppm
*Nickel - 1 ppm
Chromium - 5 ppm

*Ag, Pb & Ni are corrected for background absorption.

5. Elements present in concentrations below the detection limits are reported as one half the detection limit, ie. Ag - 0.1 ppm

FEB./80

GEOCHEM PROCEDURES

PPM Antimony: a 1.0 gm sample digested with conc. HCl in hot water bath. The iron is reduced to Fe^{+2} state and the Sb complexed with I^- . The complex is extracted with TOPO-MIBK and analyzed via A.A. Correcting for background absorption 0.2 ppm \pm 0.2 Detection limit.

PPM Arsenic: a 1.0 gram sample is digested with a mixture of perchloric and nitric acid to strong fumes of perchloric acid. The digested solution is diluted to volume and mixed. An aliquot of the digest is acidified, reduced with KI and mixed. A portion of the reduced solution is converted to arsine with $NaBH_4$ and the arsenic content determined using flameless atomic absorption.

Detection limit - 1 PPM

PPB Gold: 5 gm samples ashed @800°C for one hour, digested with aqua regia - twice to dryness - taken up in 25% HCl⁻, the gold then extracted as the bromide complex into MIBK and analyzed via A.A.

Detection limit - 10 PPB

ASSAY PROCEDURES

Gold: - Fire Assay Method.

0.5 assay ton sub samples are fused in litharge, carbonate and silicious fluxes. The lead button containing the precious metals is cupelled in a muffle furnace. The combined Ag & Au is weighed on a microbalance, parted, annealed and again weighed as Au. The difference in the two weighing is Ag.
