BOB 4	20	89287	5068	August 16, 1985

## INTRODUCTION:

The Bob #1-4 Claims were staked to cover an area of soil samples anomalous in gold and arsenic. These samples were part of a regional geochemical sampling program.

Grid sampling was done from September 20-28, 1983 and is described by Rein Turna (1984). This summer from May 4 to June 15 a detailed grid was established with rock, soil sample and soil profile samples being taken. For assessment purposes only the work done after the BOB #1-2 claims expiry date of May 20 is reported as expenditures, although all maps are complete.

Location and Access: The claims are located 75 km west of Quesnel, B.C. and accessible along an excellent system of paved and gravel logging roads.

Topography: The area of the BOB claim group is characterized by low rolling hills with elevations between 900-1170 meters. Michelle Creek which flows eastward through the claims forms a broad low area of swamp and thick glacial till deposition. Otherwise drainage is good with the gentle relief cut by erosional gulches.

The claims are forested by coniferous (Spruce, Pine) and deciduous (alder) trees from new post forest fire growth to mature harvestable stands.

## GENERAL GEOLOGY:

The area was originally mapped by H.W. Tipper with the Geological Survey of Canada in 1957 (Map 12-1959). Tipper's mapping is correct with one set of outcrops being found on a prominent hill between L30-L42N, 10-25W (see Figure 2 for rock sample locations) and another smaller area of outcrop between L35-L40N between 0-3W. The former area is polymitic conglomerate consisting of rounded semi spherical clasts of predominately light grey creamy

chert and lesser dark grey black chert. The matrix seems to be a medium grained poorly consolidated quartz rich sandstone. The conglomerates form massive outcrops with only rare bedding being indicated by differential erosion or very thin lensy sandstone interbeds, indicating a flat to  $10^{\circ}$ - $15^{\circ}$  south dip with an east-west trend.

Rare narrow (<1m) quartz-feldspar rhyolite porphyry dykes trending N-S dipping vertically have been observed cutting the conglomerates.

The latter outcrop area along the east side of the claims is massive basalt lava-flows and breccia.

Tipper has indicated the conglomerates are Juro-Cretaceous in age with the basalts being part of a Tertiary Paleocene event.

#### GEOCHEMICAL SURVEY:

All samples from 1984 and previous work including rock, soil and soil profiles are plotted on Figures 2, 3, 4. About half the 1984 soils were run for copper but as it added nothing to the definition of the anomalous area copper analysis was dropped, the copper values are not plotted. Best soil anomaly definition and rock correlation is given by Au and As (see Figures 3, 4). All soils and soil profile samples were run Au, As, rock were run Au, As often along with Ag, Pb, Zn, Cu, Hg, Sb. No whole rock analysis or detailed mineralogical studies have been done. Soil profile depths and locations are on Table #2. Gold (Fig. #3) values were contoured at a 30ppm contour while arsenic (Fig #4) values were at 50 and 100 ppm.

## FIELD METHODOLOGY

Soils: Soil sampling was done using a Swedish tree planting maddock which serves doubly well as a soil sampling implement. Soils were taken at a 20cm depth in a typically poor residual "B" horizon, developed in silty clayey to silty sandy till. Samples were taken on compassed, hip chained lines, at 50m intervals, lines were cut on a east-west orientation about 150-200m apart. About  $\frac{1}{2}$  kg. samples were collected in kraft envelopes and sent unprepared to Bondar-Clegg Co. Ltd. for analysis.

Soil Profiles: Pits were dug under some of the more interesting anomalous soil samples (Table #2) Generally they were dug to 0.7 - 1meter depth with 2-3 samples being taken, usually at the 0.4 meter depth the top of the till under the poor "B" soil, and at the pit bottom. About  $\frac{1}{2}$  kg samples were collected in kraft envelopes and sent unprepared to Bondar Clegg Co. Ltd. for analysis.

Rocks: Rock sampling was concentrated within the conglomerate unit where there was outcrop coincident with anomalous soil values. Generally the outcrops were chip sampled over 10-25m widths in a E-W direction. Small outcrops, the odd fracture zone, and boulders were grab sampled. (Table #3). Samples of 2-4kg weight were bagged and sent to Bondar Clegg Co. Ltd. for analysis.

## Laboratory Methodology:

Soil and silt samples were dried at  $60^{\circ}\text{C}$  and seived to -80 mesh. Rock samples were pulverized to -150 mesh.

### Geochemical Analysis for Cu, Pb, Zn, Mo, Ag.

0.5 gram samples are digested in hot aqua regia and diluted with demineralized water. Extracted metals are determined by atomic absorption. Background correction is made for Ag and Pb.

### Geochemical Analysis for Au:

10.0 grams samles that have been ignited overnight at  $600^{\circ}\text{C}$  are digest in hot aqua regia and diluted with demineralized water. Determination is by atmomic absorption.

Geochemical Analysis for As:

As is extracted from the sample using HC1O<sub>4</sub>-HNO<sub>3</sub> arsine. Method of analysis is solourimetric.

Geochemical Analysis for Sb:

Sb is determined by energy dispersive x-ray flourence.

Geochemical Analysis for Hg:

0.5 gram samples are digested in aqua regia and diluted with 20% HC1. Hg is determined by closed cell, flameless atomic absorption.

DISCUSSION

A largely Au, As soil anomaly is situated within the west half of BOB 2 claim (L30-40N) (Fig.3,4). To the south the anomaly narrows but persists at least to L20N. Northerly the anomalous values on L42N, L45N, L45N (Fig. 3,4) are partial caused by down slope migration and dispersion from the hill and cliff on the western half of L40N. The swamp and glacial sediment of Mitchelle Creek mask bedrock values. Au, As anomalous values on L47N, L49N, L52N are either down downslope or spurious. From L55N to L73.5N clusters of Au, As values occur in the mid to west half of BOB 3 and BOB 4 claims. The As, Au value inter relationship is identical to the Au, As values on the BOB 2 claim and the source is believed to be common.

The high geochemical values in soils were checked by soil profiling with samples taken usually at 0.3-0.4 and 0.7-1.0m depth. Correlation is good, As shows enhancement with depth.

An east west cliff running parallel to L40N from 15-22W as well as scattered out crop from L40N-L34N in the 15-22W area was partially rock sampled. Gold, arsenic values were found persistently in the sampled conglomerates from grab samples to 30m chip samples of outcrops. Minor surficial limonitic and hematitic alteration was noted, there was no sulfide mineralization.

CONCLUSIONS:

Au, As values in soils have been confirmed by soil profiles and rock sampling.
