Composite Geophysical Interpretation and Gold Geochemistry	5

INTRODUCTION

The Venus group of claims include two gold mines, the Venus and the Juno, which produced limited tonnages of ore around the turn of the century and again during the '30's. A geochemical survey was initiated during 1983 and completed in 1984 to determine the extensions of the known veins and to determine if there were any additional veins on the property. The geochemical data from the 1983 program have been incorporated in this report to assist in the interpretation of results but the costs have not been included for assessment purposes.

A geophysical survey was carried out in 1984 to clarify the geochemical results and to obtain a better understanding of the structure of the gold-bearing areas.

PROPERTY DESCRIPTION, LOCATION, AND ACCESS

The property consists of eight contiguous claims (six reverted crown grants and two located claims, all held by record) as listed under Summary of Claims and shown on Figure 1. The claims cover approximately 120 hectares on the north slope of Morning Mountain at $49^{\circ} 27'$ N. Lat. and $117^{\circ} 20'$ W. Long., about 4.4 km. by air southwest of Nelson, B.C., in the Nelson Mining Division. The claims lie at an average elevation of 1600 metres.

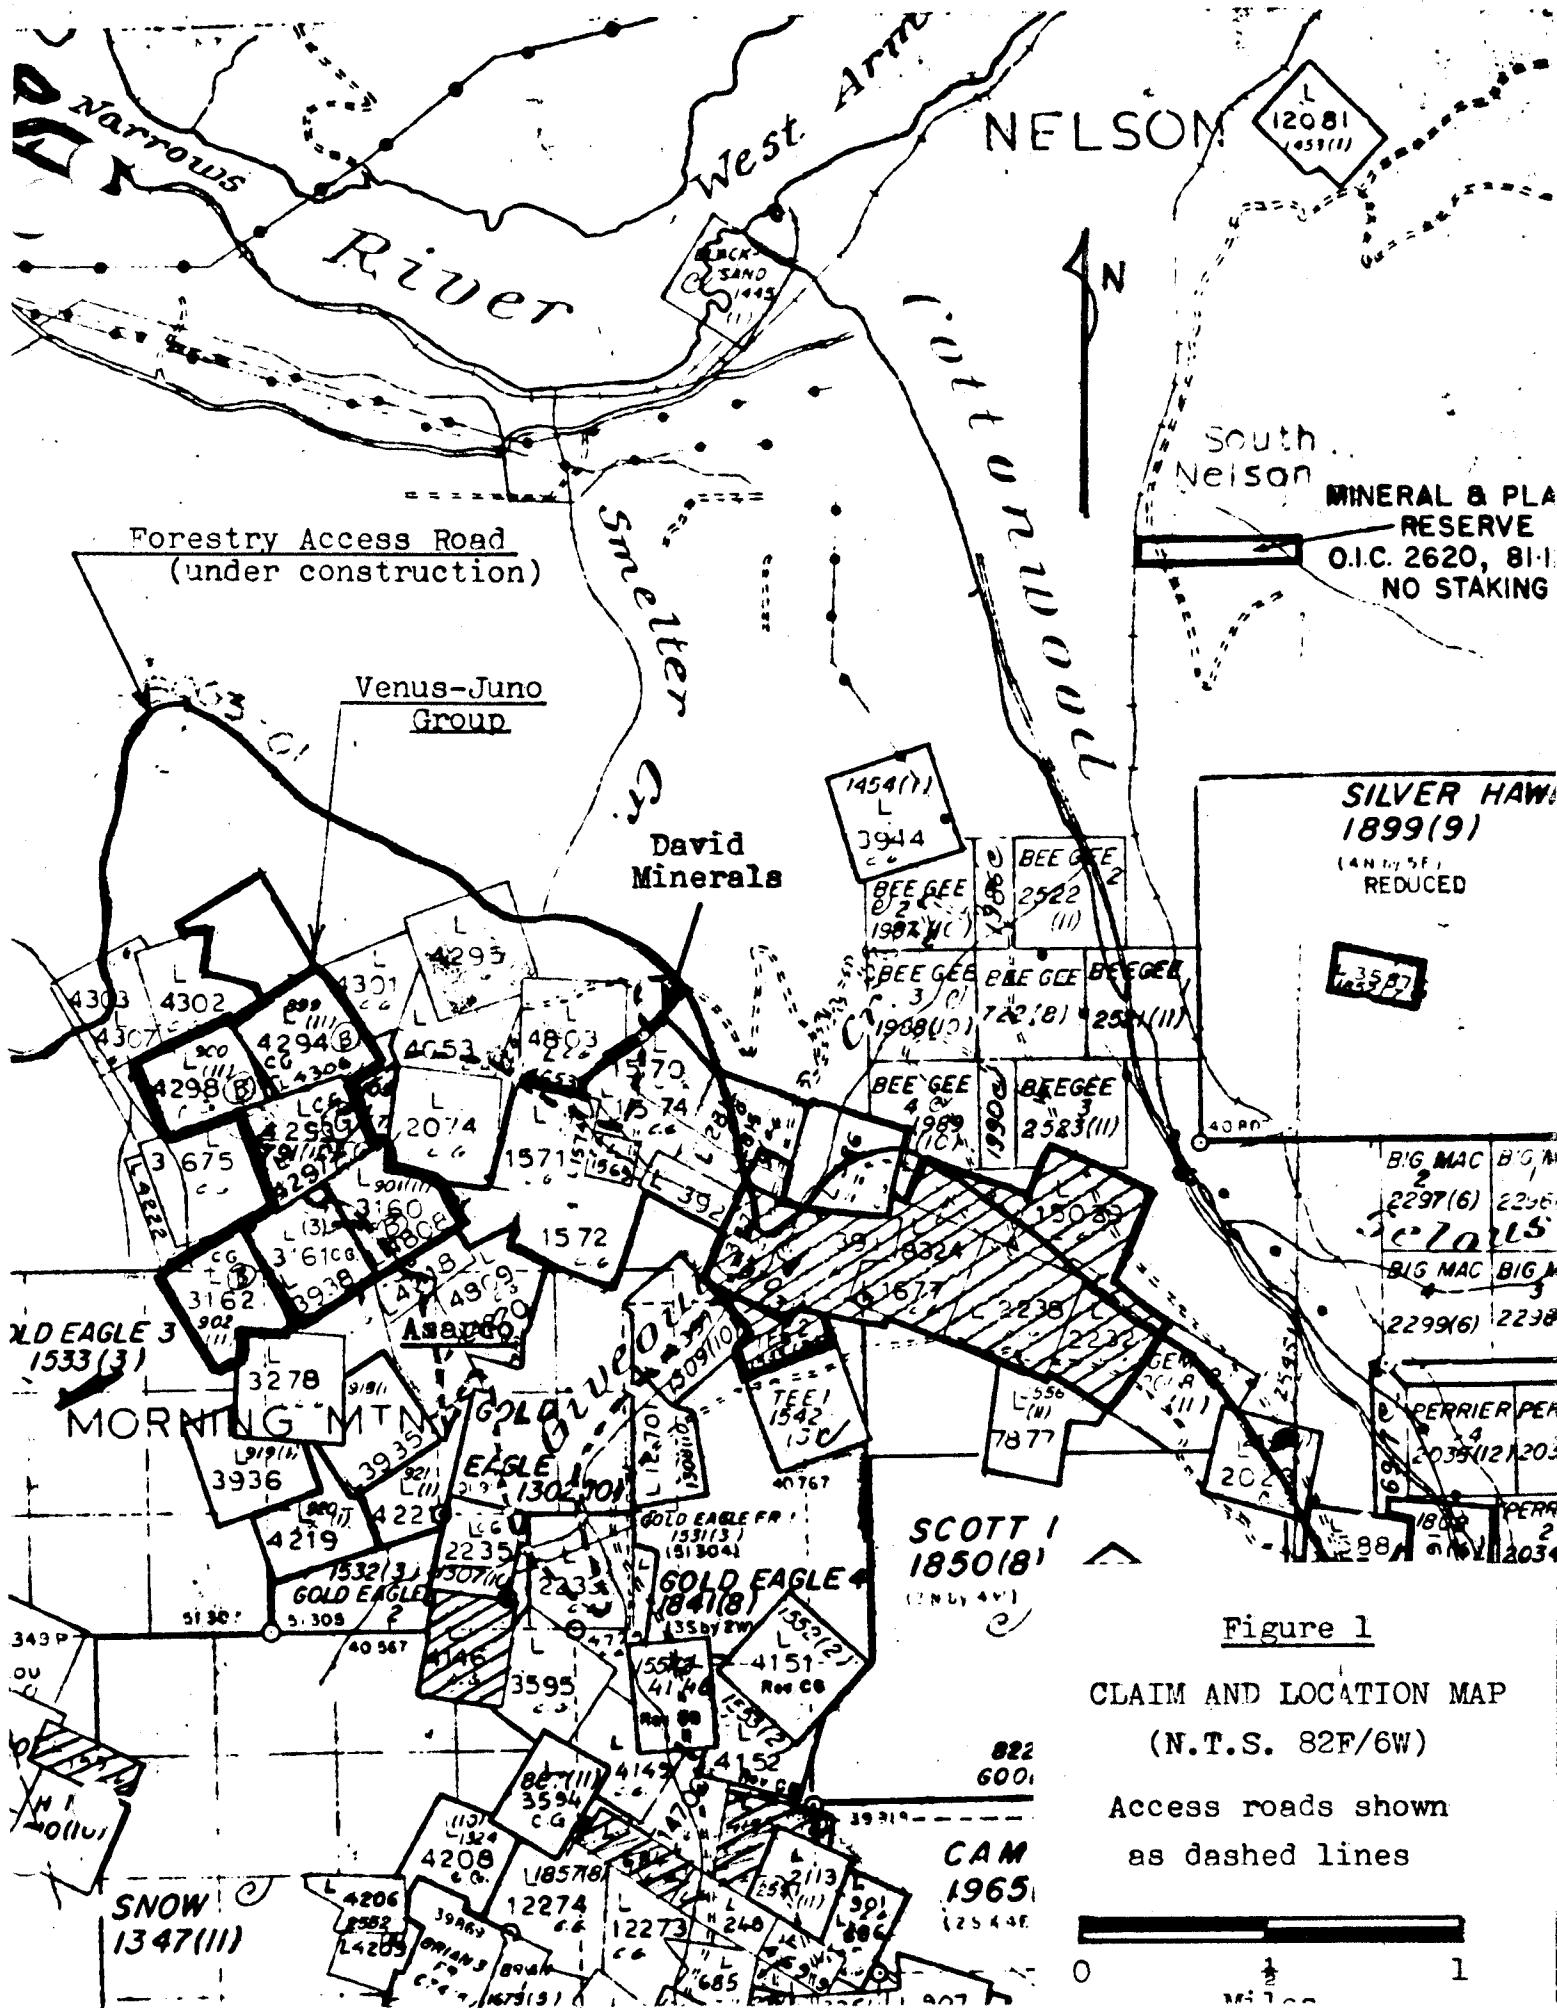

Figure 1

CLAIM AND LOCATION MAP
 (N.T.S. 82F/6W)

Access roads shown
 as dashed lines

The property is accessible by 12 km. of highway and forestry access road and 2 km. of mining road from Nelson. An alternate but longer route runs up Giveout Creek; both routes are shown in Figure 1.

HISTORY

The Venus and Juno mines were actively developed from 1900 to 1904. Government records show that the combined production for the two mines was 5,967 tons grading 0.577 oz. gold and 0.514 oz. silver. The mines were operated by leasers in the '30's who shipped 210 tons of ore ⁽¹⁾, and by Noble Five Mines who shipped one car of ore ⁽¹⁾. The property is now owned by Ernesco Resources Ltd. who are investigating the economic potential of the area.

The Venus vein has not been traced uphill beyond a fault which cut off the ore nor has it been followed down dip below the lowest workings. The Juno vein has not been explored for more than 200 metres on strike or 100 metres down dip. Both vein structures may contain viable ore-shoots and the property is in a favourable geological environment for the discovery of other vein systems, being on or near the convex nose of a granodiorite intrusive ⁽²⁾.

GEOLOGY

The property is underlain by basic volcanic flows (augite porphyry, andesites, etc.) of the Rossland Volcanic Group which have been intruded by various phases of the Nelson Batholith^(1,3). (Figure 2) Quartz veins, varying from stringers to one metre in width, occupy shear zones in both the volcanics and the granodiorite. These veins carry pyrite with minor galena and sphalerite. Values are mainly in gold with some silver.⁽³⁾.

The Venus vein, which cuts both the volcanics and the granodiorite, strikes N.25°-40° W. and dips northeast at 20 to 40 degrees. The vein reportedly followed a basic dike in the lowest adit⁽¹⁾. The Juno vein is entirely within the volcanics and is almost at right angles to the Venus vein. It strikes N.60°E. and dips 55°-60° northwest.⁽³⁾ The two veins should intersect but the juncture was not located by any of the old workings.

All the mine openings, except the adit on the Juno, are caved in and little can be learned of the conditions obtaining in the Venus mine.

The surface is covered extensively by overburden and rock outcrops are rare in the mine area.

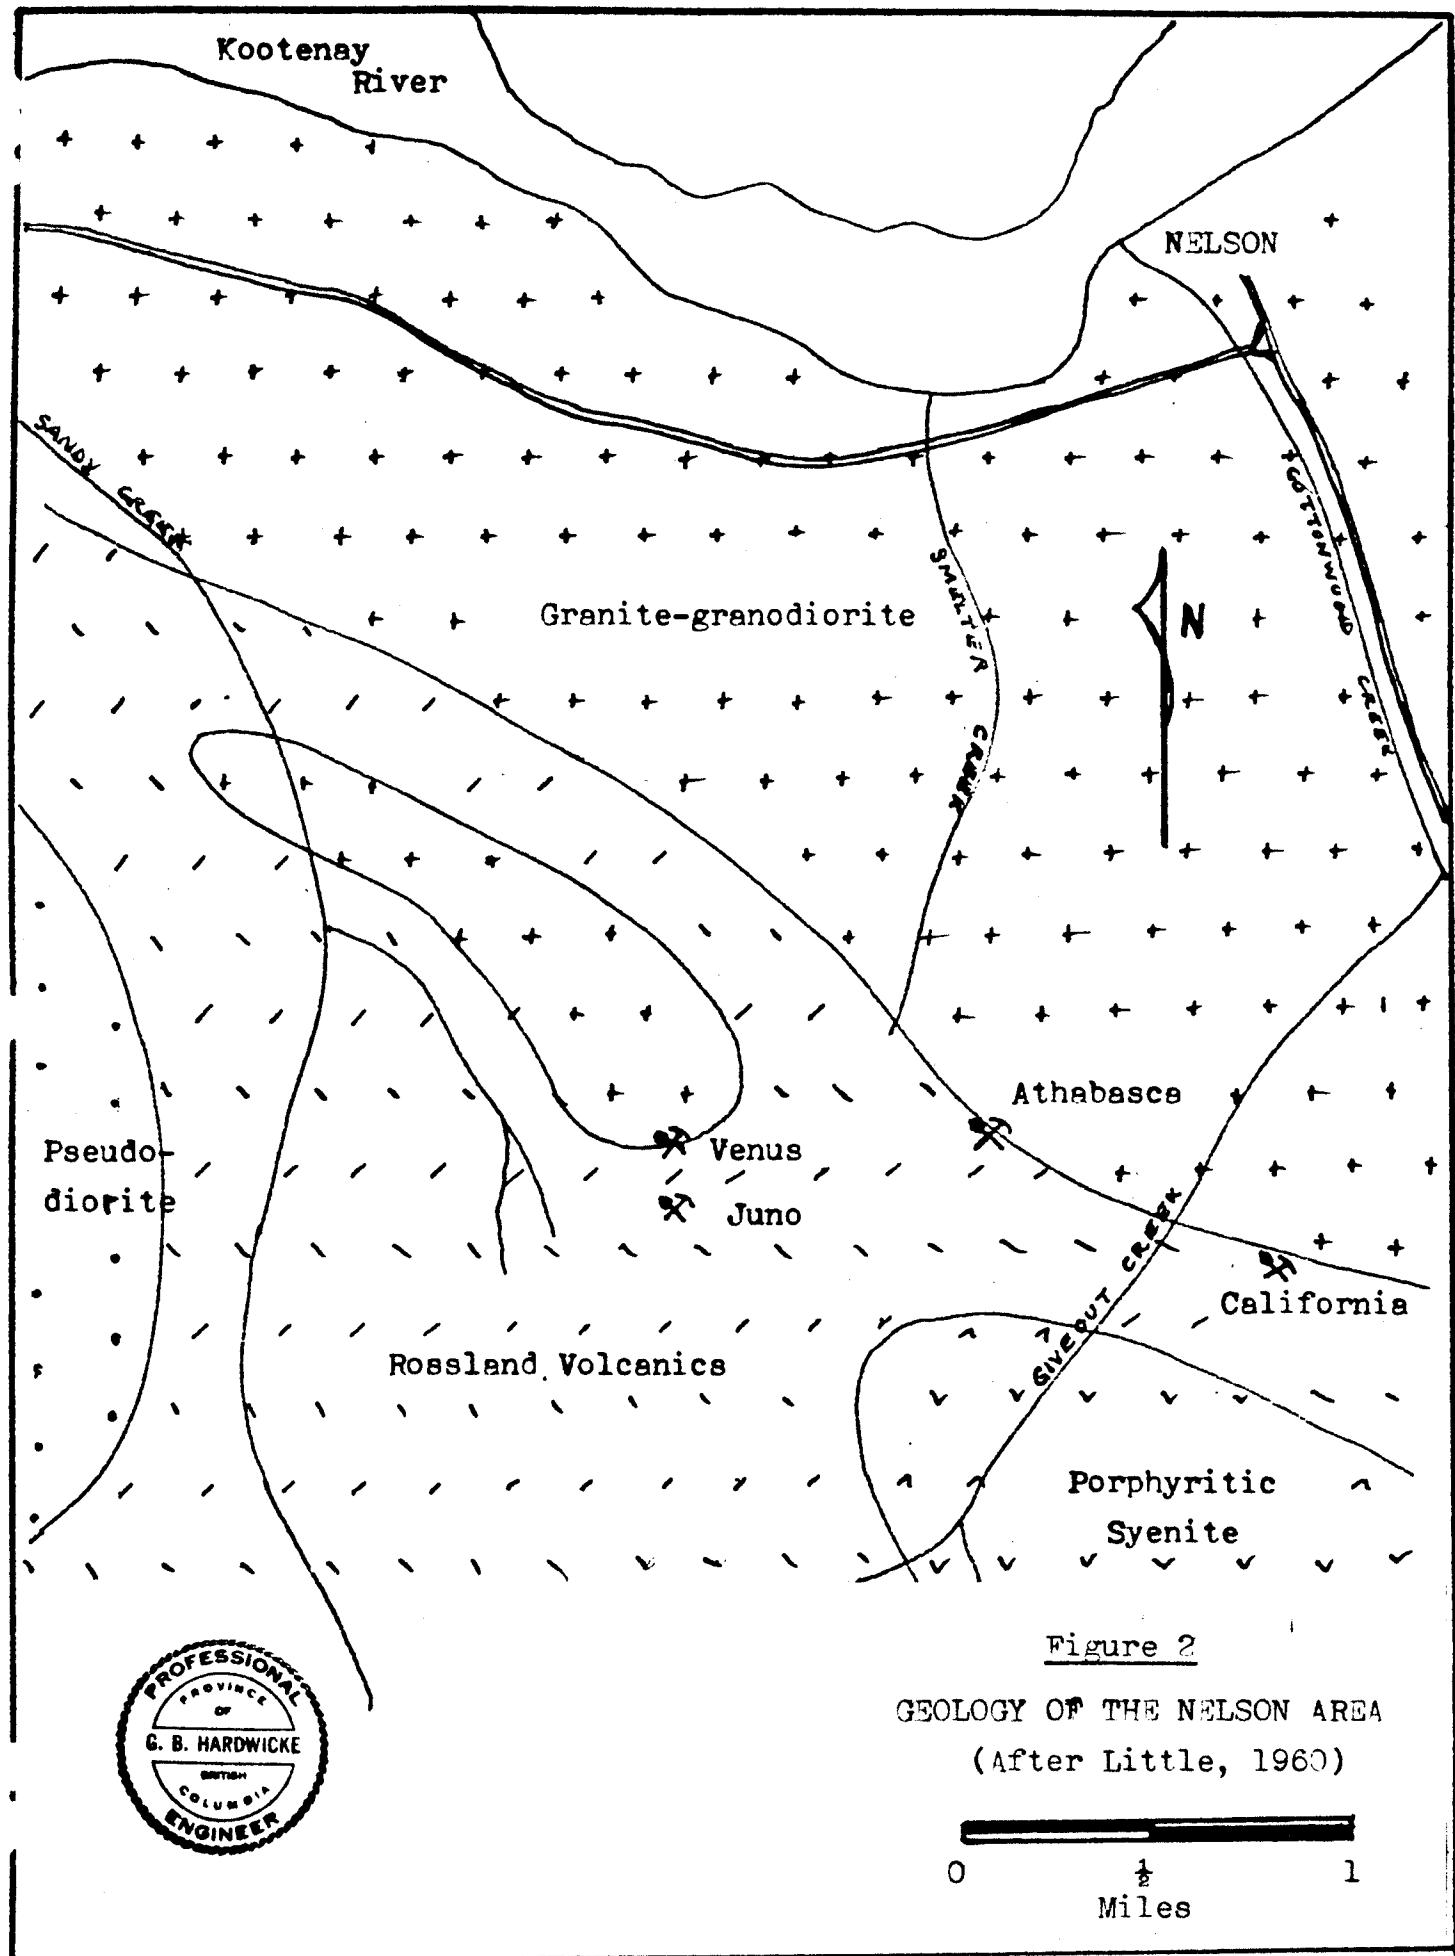

Figure 2

GEOLOGY OF THE NELSON AREA
(After Little, 1960)

SURVEY CONTROL

The survey records of the old crown grants were obtained and a base map was prepared for the geophysical and geochemical surveys. Most of the old claim posts were located on the ground and the grid lines were tied into these reference points by chain and compass.

SUMMARY OF EXPLORATION WORKGeochemical Survey

Approximately 5.2km. of line were established with the lines oriented so as to cross both the Venus and Juno veins and any complimentary structures which might exist. Line spacing was 90 metres except where fill-in lines were required. Samples were taken at 15 metre intervals by trowel from the B horizon and were analyzed for gold, silver, lead, zinc and copper. A total of 372 samples were taken in 1984 and the results were combined with the results from 309 samples taken in 1983 (4.8km.of line) for interpretation purposes.

The A horizon on the property ranges from 4 to 30 cm. in thickness and the B horizon ranges from 3 to 10 cm. in thickness.

Claims which were soil sampled during 1984 were the Kirkwall, Juno, Venus, Orion, Jupiter, Bee and Bee Fr.

Geophysical Survey

A geophysical survey was carried out by Interpretex Resources Ltd. of Vancouver, B.C., and a copy of their report is appended to this report. This survey utilized the grid lines established for the geochemical survey and was designed to investigate the area of highest soil sample assay values. Some 267 readings were taken with a magnetometer and EM-16 over approximately 4 km. of line on the Venus, Orion, Jupiter, Bee and Bee Fr. claims.

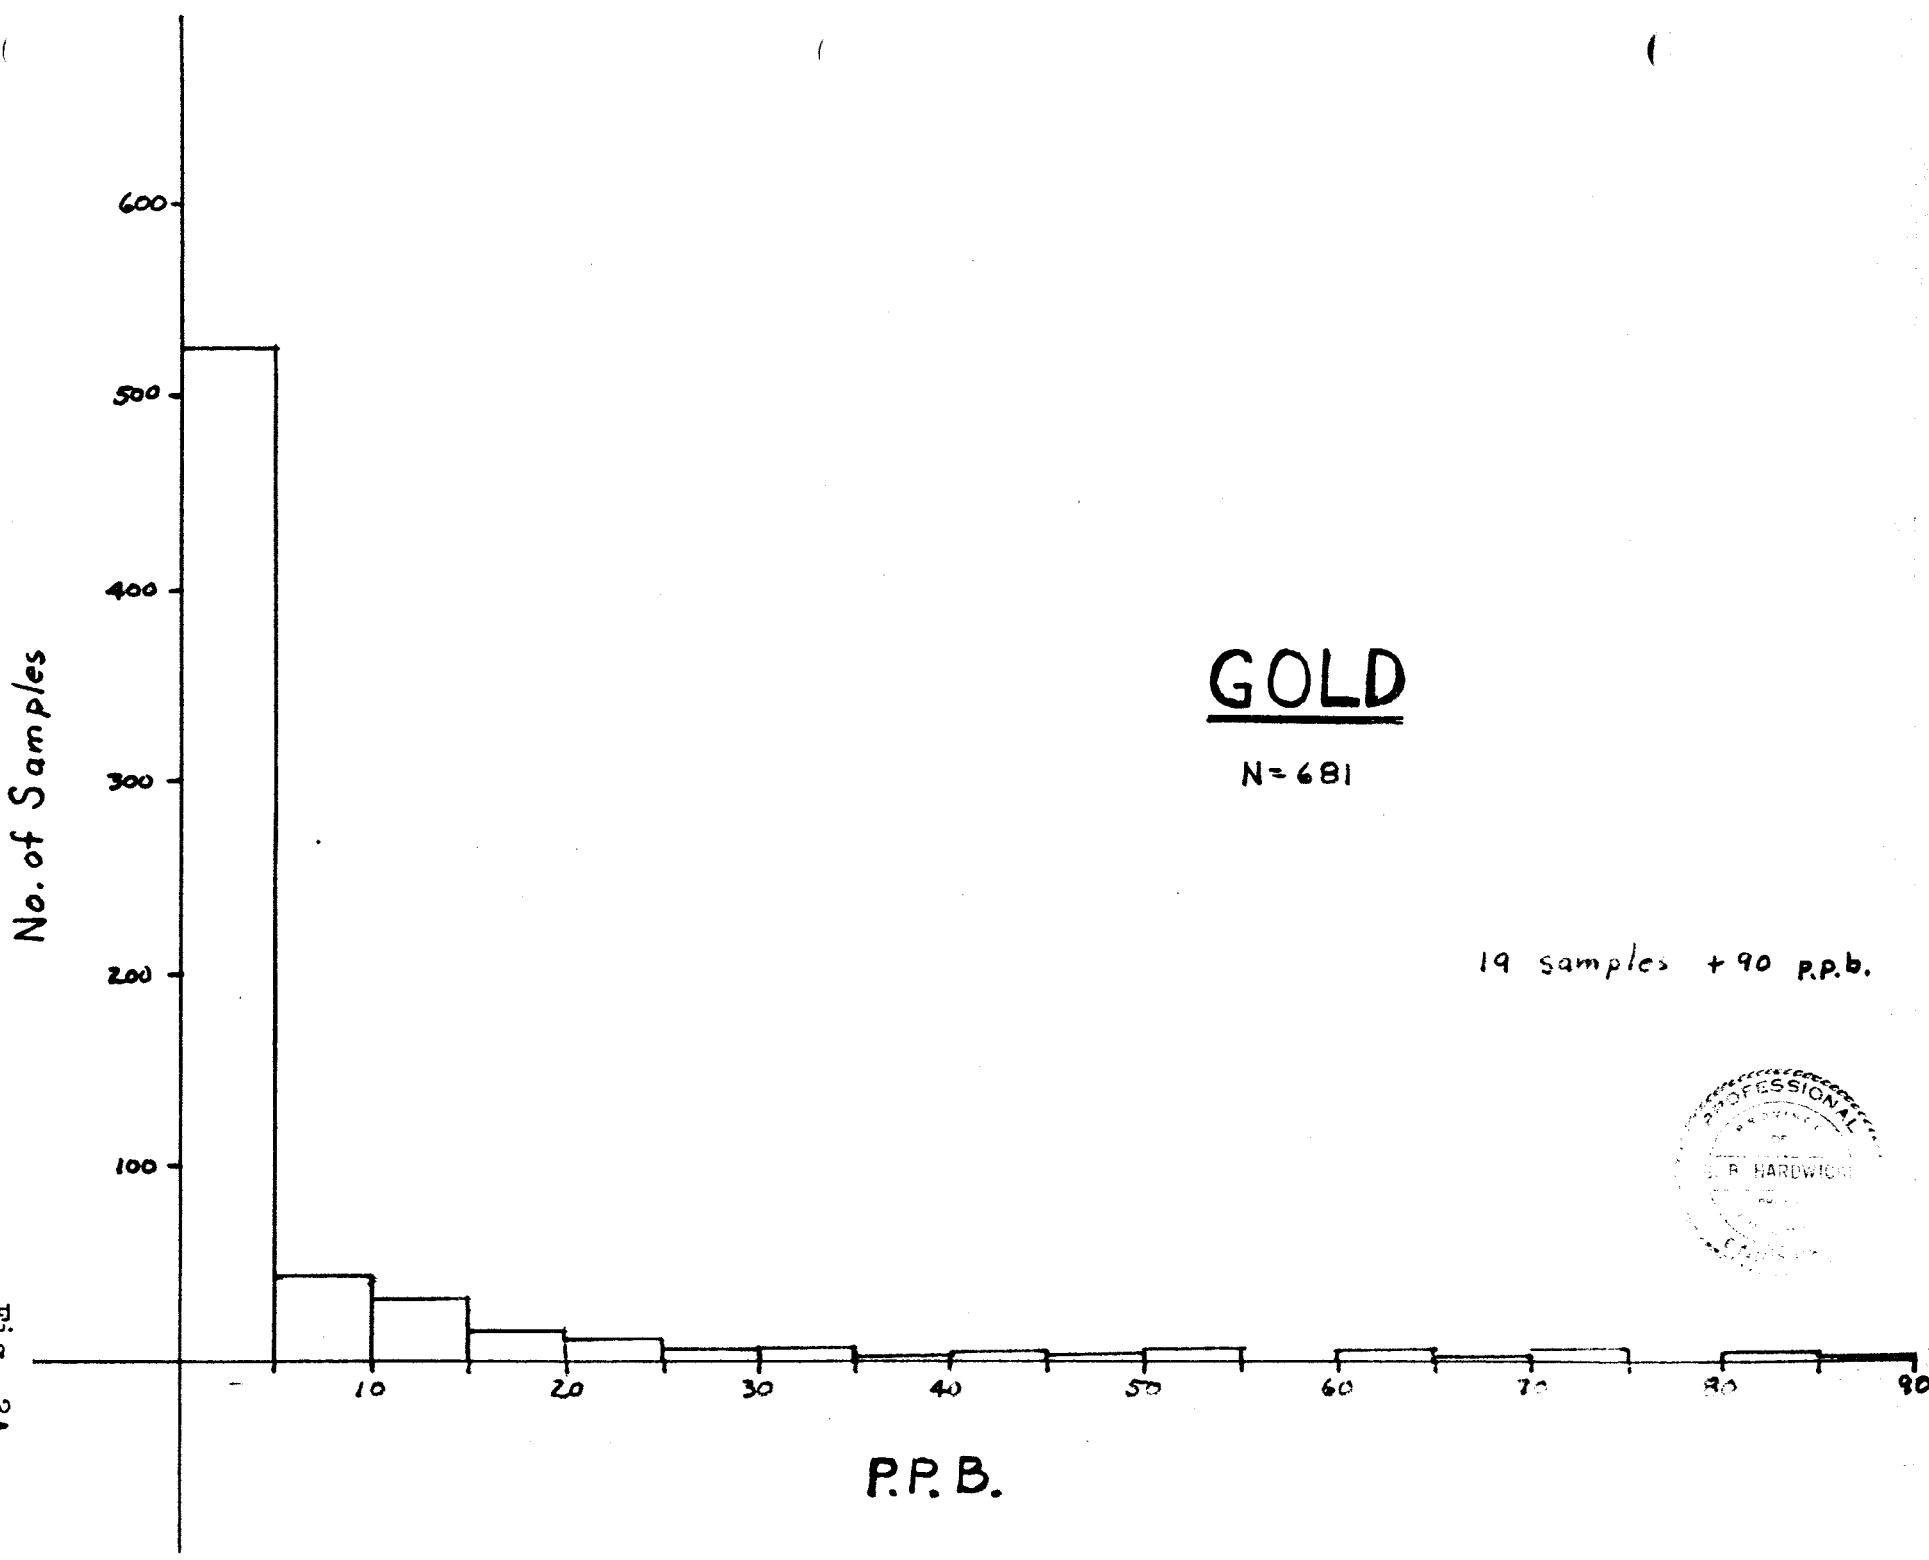

DISCUSSION OF GEOCHEMICAL RESULTS

Based on the type of mineralization known to occur in the area, the most significant elements which have been plotted for the geochemical study are gold, silver, lead and zinc.

Histograms and frequency distribution diagrams for these elements (Figures 3 to 6, A and B) suggest the following breakdown for background, weakly anomalous, moderately anomalous and strongly anomalous values :

<u>Gold</u>	Background	0 - 15 p.p.b.
	Weakly anomalous	20 - 35 p.p.b.
	Moderately anomalous	40 - 60 p.p.b.
	Strongly anomalous	+ 60 p.p.b.
 <u>Silver</u>	Background	0 - 1.1 p.p.m.
	Weakly anomalous	1.2 - 2.4 p.p.m.
	Moderately anomalous	2.5 - 3.4 p.p.m.
	Strongly anomalous	+ 3.4 p.p.m.
 <u>Lead</u>	Background	0 - 30 p.p.m.
	Weakly anomalous	31 - 40 p.p.m.
	Moderately anomalous	41 - 60 p.p.m.
	Strongly anomalous	+ 60 p.p.m.
 <u>Zinc</u>	Background	0 - 150 p.p.m.
	Weakly anomalous	151 - 200 p.p.m.
	Moderately anomalous	201 - 300 p.p.m.
	Strongly anomalous	+ 300 p.p.m.

Two areas with high geochemical values in all metals were noted. One, north of the portal of the Juno adit, is possibly due to contamination from mining operations and has not been investigated as yet. The other, larger area to the northwest of the Venus No. 8 adit was trenched at three locations with a backhoe but bedrock was not found. This area is underlain by basal till in excess of four metres in thickness and drilling will be required to

determine the source of the mineralization. Quartz fragments, some of them mineralized with pyrite and galena, were found in the excavated material.

Outside of these two areas the lead, zinc and, to some extent, the silver anomalies do not coincide closely with the gold anomalies.

Anomalous gold values found on the Kirkwall claim appear to line up with the Juno vein and should be followed up. A zone of anomalous gold values trending across the Orion claim should be investigated since it coincides with an EM conductor.

Soil geochemistry results are shown on Plans 1 to 4 ; Plan 5 shows the gold geochemistry results superimposed on the geophysical interpretation map, together with the location of the old adits and the approximate position of the volcanic-granodiorite contact.

DISCUSSION OF GEOPHYSICAL SURVEY RESULTS

The geophysical survey indicates the presence of three EM conductors (see appended report). The strongest conductor lies just to the northwest (downslope) from the

area of coincident geochemical highs near the Venus No. 8 adit. Another coincides with a zone of high gold values trending across the Orion claim, while the third, near the south side of the Jupiter claim, is at the ends of the geochemical grid lines and may or may not be associated with geochemical highs. All are worthy of further investigation.

Magnetometer highs on the south ends of lines 6 & 7 (see Plan 5) correspond with the assumed contact between the volcanics and the granodiorite.

A line of magnetic highs trending southeast across the Jupiter claim may indicate the presence of a basic dike (Interpretex Resources, personal communication). (See Plan 5). Since the Venus vein was known to follow a basic dike⁽¹⁾, it is possible that this dike, if present, may also be accompanied by a vein.

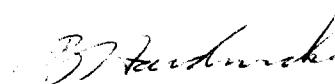

CONCLUSIONS

It may be reasonably concluded that the results of the geochemical and geophysical surveys warrant the trenching and/or drilling of the known anomalies where EM and/or magnetometer anomalies coincide with high gold geochemical results.

CERTIFICATE

I, G.B.Hardwicke, Mining Engineer, of Box 637, Grand Forks, B.C., hereby certify that :

1. I am a graduate of the University of British Columbia, B.A.Sc. (Mining), 1955.
2. I am a registered Professional Engineer in the Province of British Columbia and have been practicing my profession for 29 years.
3. This report is based on work performed by myself or under my direct supervision.
4. I have not received, nor do I expect to receive, directly or indirectly, any interest in the subject property or in any securities of any company which may develop the property.

1. SUMMARY

A number of mainly weak (compared to other VLF EM surveys) anomalies were found by this survey. A strong anomaly at line 8, station 25 may be coincident with tracks in an old adit but is believed to be a bona fide bedrock conductor and to continue westward.

Other conductors in the north and south extremities of the surveyed portions of lines 8, 10, 11, 12 and 13 may be related to structure.

A southeast magnetic high trend may be related to a southeast geochemical trend. Anomalies in the vicinity of these trends and associated with magnetic highs and lows are enhanced in priority.

A more basic rock type is suggested by steep magnetic gradients in the south portions of lines 6 and 7.

Conductors should be followed up by trenching or drilling. Priorities suggested are subject to revision by additional geological or geochemical knowledge. The possibility of clay as the cause of conductivity in some cases warrants the use of inexpensive initial follow-up methods.

2. INTRODUCTION

This report pertains to VLF electromagnetic and total field magnetic surveys carried out August 23, 1984 on the VENUS property for Ernesco Resources Ltd. Survey was performed on geochemistry lines which were established previously and oriented Az 014°.

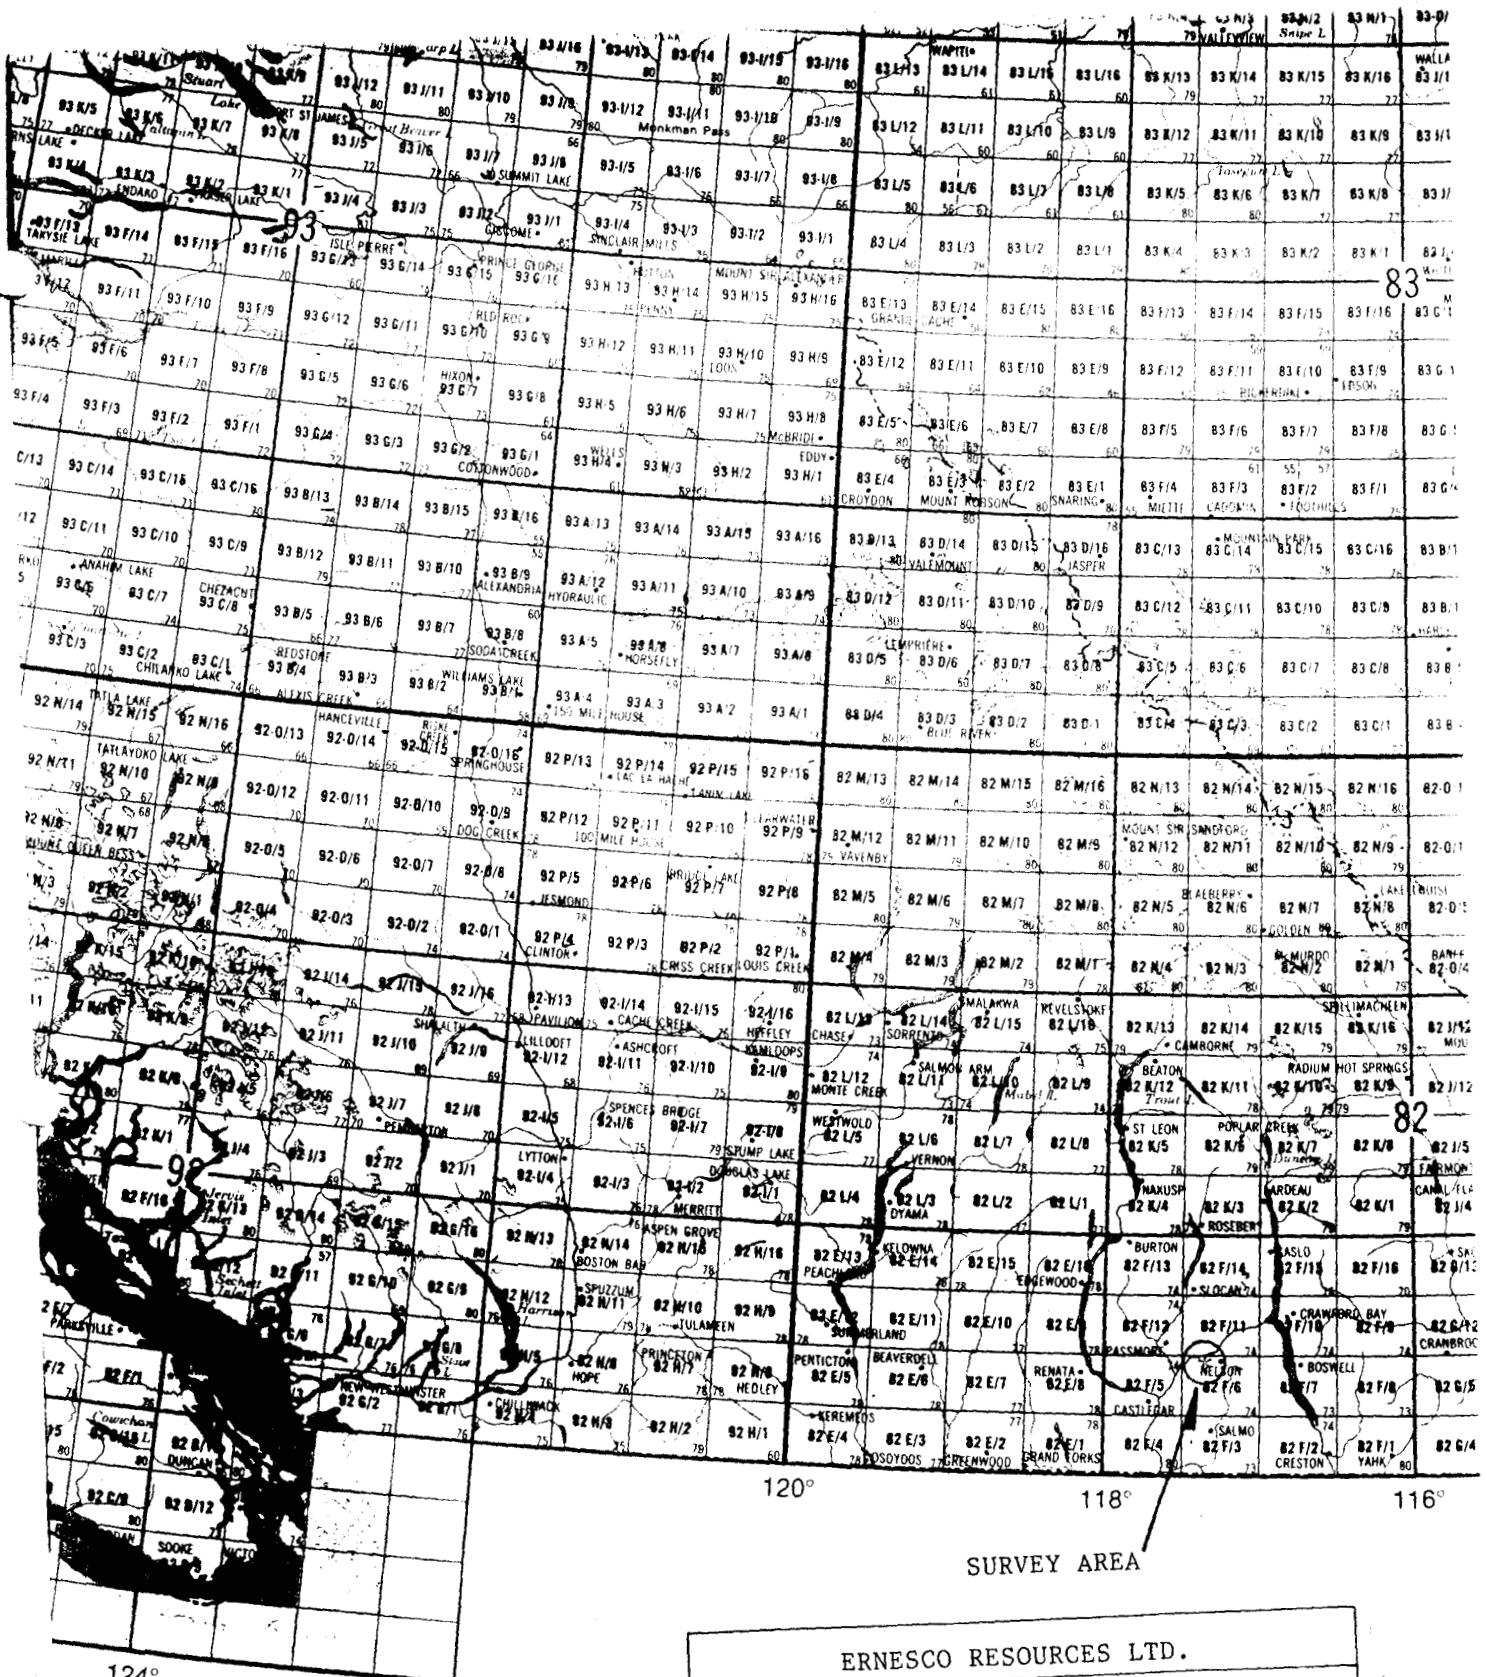

The property is located near Nelson, B.C. (Figure #1) with access by forestry and mining roads using four wheel drive trucks.

Geochemistry lines "6" through "13" inclusive were surveyed at stations as shown on Geophysical Interpretation Map (Figure #2). All readings were taken at 50 foot intervals. Some lines were lengthened, by pacing, in order to complete anomalous responses.

3. OBJECTIVES

The objectives of the surveys were as follows:

- to determine if portions of the structurally related gold bearing quartz vein were conductive
- to outline additional areas of conductivity
- to investigate any correlation between electromagnetic or magnetic results with geochemical results
- to suggest priorities for additional follow-up exploration.

4. METHOD

A Geonics EM-16 and Exploranium G-816 magnetometer were used for the surveys. Variations of the earth's magnetic field were controlled using the "tie-back" method and application of linear drift correction curves to the data. No corrections were made to VLF EM data.

In-Phase and Out-of-Phase VLF EM readings (in percent) were taken using the Annapolis, Maryland and Cutler, Maine VLF transmitting stations. Cutler was used only on line 6 when Annapolis temporarily shut down. Direction to the two stations was nearly identical thus data were deemed to be equivalent. All readings were taken facing in a northerly direction.

In-Phase and Out-of-Phase VLF EM readings were profiled and presented on Figure #3.

An "enhanced" first derivative filter was applied to all In-Phase readings. The enhanced derivative values (normal derivative times π), shown on Figure #4, were then contoured and presented on Figure #5.

All magnetic readings were taken using a staff modified for mountain use. Corrected total field magnetic values were posted on Figure #6, then contoured and presented on Figure #7.

5. DISCUSSION AND CONCLUSIONS

VLF EM data show a consistent negative bias (all negative In-Phase readings - Figure #3) due to a downward topographic slope to the north. A number of anomalies of various strengths can be seen superimposed on the negative bias. All anomalies show low conductance and most are weak relative to "typical" VLF EM response in other areas. The only strong response was found on line 8 at approximately station "25". Although this anomaly may be coincident with an old adit and therefore could be caused by tracks in a tunnel, the writer believes that its strength and abrupt termination between line 8 and line 9, plus possible correlation with anomalies on lines 10 and 11, signifies that the anomaly could be due to conductive material within bedrock. This conductor "system", shown on Figures #2 and #5 is considered high priority for follow-up exploration.

Another noteable conductor system can be seen on Figures #2 and #5 near the north ends of the surveyed portions of lines 8, 11, 12 and 13. Although weaker than that on line 8, station 25, these anomalies are strong relative to most others in the area. The system may represent a west-north-west trending structural feature. It is considered second priority for follow-up.

A group of anomalies near the south ends of lines 10, 11, 12 and 13 form another "system" which also could reflect structure and is considered third priority for follow-up.

Weak anomalies which appear to correspond to geochemical highs are considered fourth priority. They are as follows:

- line 10 station 20 (approx.)
- line 9 stations 5 and 7 (approx.)
- line 6 station 35 (approx.).

Other VLF EM anomalies, unless enhanced by additional information, are considered low priority for follow-up exploration.

Magnetic results indicate a southeast magnetic high trend (shown by "M" symbols on Figure #2), that appears to occur slightly to the south of and sub-parallel to a south-east geochemical anomalous trend. Furthermore, some anomalous magnetic lows seem to correlate with geochemical anomalies.

For this reason individual E.M. anomalies in the vicinity of the magnetic highs and lows can be considered as enhanced beyond priorities originally stated above.

Steep magnetic gradients in the south portions of lines 6 and 7 indicate a more basic rock type in this region. The contact between more basic rocks (volcanics ?) and granitic rock is believed to be in the vicinity of stations "57" and "62" on line 6 and around stations 105 and 106 on line 7. A conductor on line 6 at stations 46 to 47 is associated with a magnetic high and should be investigated for the presence of pyrrhotite.

6. RECOMMENDATIONS

Conductors and anomalies outlined by the survey should be followed up by trenching or drilling to determine the cause of conductivity and relationship to gold mineralization. Priorities listed above can serve as a guide for follow-up but may change according to additional geological or geochemical information. The possibility of clay layers as the cause of conductivity must be considered in some cases and thus an inexpensive method of follow-up (such as trenching by back-hoe or explosives) should be considered first.

GEOCHEMICAL LABORATORY METHODOLOGY

Acme Analytical Laboratories Ltd.
352 E. Hastings Street
Vancouver, B.C., V6A 1R6

Sample Preparation

1. Soil samples are dried at 60°C and sieved to -30 mesh.
2. Rock samples are pulverized to -100 mesh.

Geochemical Analysis

For : Ag., Pb., Zn. and Cu.

0.5 gram samples are digested in hot dilute aqua regia in a boiling water bath and diluted to 10 ml. with demineralized water. Extracted minerals are determined by Inductively Coupled Argon Plasma (ICP).

For : Au.

10.0 gram samples that have been ignited overnight @ 600° C are digested with hot dilute aqua regia and the clear solution obtained is extracted with Methyl Isobutyl Keytone (MIBK). Au. is determined in the MIBK extract by Atomic Absorption using background correction.
