1.0

INTRODUCTION

The Precisely and Casa claims cover an area of argillite and andesite volcanics, both of the Nicola Formation. The argillite is brecciated and locally silicified indicating that hydrothermal activity has altered the sediments.

Work described in this report consists of preliminary geological mapping of the entire property, and more detailed mapping of the areas of brecciation and silicification.

2.0

LOCATION, ACCESS AND TOPOGRAPHY

The Precisely and Casa claims are located southwest of Vidette Lake, approximately 62 kilometres northwest of Kamloops, British Columbia. Access is via the all-weather Deadman River road which joins the Trans-Canada Highway eight kilometres west of Savona. The property itself is well covered by a network of 4-wheel drive roads, motorcycle trails, and cattle paths.

The property lies near the southern end of the Fraser Plateau at an average elevation of approximately 1,100 metres. Topography is subdued within a range of about 150 metres. Vegetation is mixed consisting of grassland and open forest of aspen and pine. Overburden is nearly continuous and outcrops are generally scarce.

4.0

HISTORY AND PREVIOUS WORK

The Precisely claims are 7 kilometres southeast of the Vidette Gold Mines where gold was discovered in 1931. From 1933 to 1940 the mine produced 54,199 tons of ore grading 0.55 oz. gold per ton, 0.86 oz. silver per ton, 0.09% copper, with minor lead (Mitchell, 1973). The mine closed when there were insufficient reserves although the faulted extension of the main production vein remained unexplored.

The first geological mapping that included the property was a study of the Kamloops map area by G.M. Dawson in 1887-1890. Cockfield (1935) who examined and described the mineralization in the vicinity of the Vidette mine in 1934, reported that prospecting during the 1930's resulted in the discovery of several similar veins in the vicinity of the Vidette Gold Mine, but none came into production. A pit in the northern part of the Precisely property may date from this period. The mine was also described in an unpublished report by J.A. Mitchell in 1973. In 1964-1965, R.B. Campbell and H.W. Tipper mapped the area at a scale of 1:250,000 and described the geology in GSC Memoir 363.

The Precisely and Casa claims were staked by M. Dickens of Savona, British Columbia following his discovery of gold bearing quartz stockworks.

5.0 WORK CARRIED OUT IN 1984

5.1 Introduction

The 1984 work program comprised geological mapping, prospecting and rock chip sampling, cutting and surveying the baseline, tieline, and crossline, establishing a grid, soil sampling on the entire grid, and orientation geophysical surveys of portions of the grid.

5.2 Geological Mapping

E.C. Grill mapped the claims at a scale of 1:10,000 (Figure 2) and determined the distribution of the Nicola volcanics and sediments, intrusive rocks, and the overlying basalt. In the central part of the property, around Beaver Lake, mineral occurrences were mapped at a scale of 1:2,500 by A.W. Gourlay (Figure 3).

5.3 Prospecting and Rock Chip Sampling

Twenty-nine man-days were spent prospecting the claims, and 65 rock chip samples were collected. The results of this survey are not available for this report.

5.4 Linecutting

A grid was established over the mineral occurrences in the central part of the property. A baseline 2.3 line kilometres long was cut and surveyed, as was a crossline and a tieline, for a total of 4.3 line kilometres. Crosslines were turned at 100 metre intervals, and a total of 14.4 kilometres were chained and flagged at 10 metre intervals.

5.5 Soil Sampling

A total of 1,286 soil samples were collected at 10 metre intervals on grid lines spaced 100 metres apart. The results of the soil geochemistry survey are not available at time of writing.

5.6 Geophysics

Surveys covering 7.95 line kilometres of magnetometry and 2.95 line kilometres of VLF-EM 16 were conducted on the grid in the vicinity of Beaver Lake. The results of these geophysical surveys are not included in this report.

6.0

GEOLOGY

The Precisely and Casa claims are underlain by andesite and argillite of the Triassic Nicola Formation (Figure 2). The Nicola is typically a dull greenish grey, fine grained "greenstone". Most often, it is comprised of clastic andesite in which the matrix is indistinguishable in colour and composition from the fragments. There are also local areas of fine grained sediments which have been derived from the volcanics, and which are often similar in appearance to the parent material.

The grid area, east of Beaver Lake, was mapped in detail at a scale of 1:2,500 (Figure 3). This area is underlain by argillite and argillite breccia that is interbedded with and overlain by andesite tuffs, augite porphyry, and minor agglomerate.

The argillite, most of which is a breccia is massive, very fine grained, and black. The breccia consists of angular fragments (>1mm) of argillite, in a quartz and calcite vein matrix. Quartz veins may be up to 1cm thick. Drusy vugs are very common, to 2cm in length, and occasionally form continuous tubes through the breccia. The argillite breccia is always iron stained, and in some places manganese stain is also present. In general, more iron staining is present where there is quartz rather than where there is calcite infilling the breccia.

The argillite and argillite breccia are overlain by and interbedded with an andesite tuff. The tuff itself is interbedded with augite porphyry and agglomerate further up section.

The tuff is generally massive and varies from very fine grained to medium grained (<.5mm to 4mm). Most of the tuffs are slightly calcareous and very commonly carry chlorite. Bedding, locally well developed, displays fining upwards sections. One outcrop coarsens upsection, and may be overturned. Bedding strikes NNE, and dips to the southeast. Anastomosing bands of dark mineral, perhaps fine grained chlorite, are common in the fine grained tuffs. Chlorite is visible in the medium-grained tuffs, commonly along incipient shears or grain boundary breaks. Some minor slickensides with chlorite were observed.

Interbedded with the tuffs are beds of augite porphyry and further up section an agglomerate of augite porphyry clasts which consist of subhedral to euhedral augite phenocrysts in an aphanitic groundmass. Augite phenocrysts range in size from 3-6mm, locally reaching 12mm. Alteration to chlorite varies from weak to extreme. Augite porphyry agglomerate, less common but still mappable, consists of subrounded to angular fragments of augite porphyry in a chloritic matrix. Fragments range in size from 2mm up to 10cm. Occasionally clasts of rounded argillite are found, and rare tuff fragments are seen.

Silicification of any of the rocks is a very local phenomenon. Pyrite occurs as disseminations in the argillite and as subhedral to euhedral crystals in the quartz veins. Locally disseminated pyrite is found in the tuff.

Regional mapping and prospecting has discovered areas of intrusive in both the southwest corner of the property and in the northeast corner. The intrusive in the southwest corner, a medium grained biotite granodiorite that has been intruded by quartz diorite, exhibits hematite, sericite, and ankerite alteration. In the northeast corner, the intrusive is also a biotite granodiorite. Several kilometres northeast of the property the Nicola Formation is intruded by granitic plutons, and in the area of Vidette Lake felsic dykes are common.

The Nicola Formation is overlain, along the south and west boundaries of the property, by Miocene plateau lavas. Olivine basalt is the most common rock type. In the main north-south valley of Deadman Creek, the plateau basalts are underlain by Miocene fine grained sediments. The basalts are commonly amygdaloidal, with quartz, calcite, and zeolite infilling.

The depth of glacial drift, which is fairly continuous over much of the Precisely property, is not known, but Campbell and Tipper note that the till is usually shallow in this area. Glacial grooving indicates that the last ice advance was toward the south at approximately 165°.

7.0

CONCLUSIONS

The Precisely claims are underlain by Triassic Nicola Formation which consists of a lower argillite interbedded with and overlain by andesite tuff, augite porphyry, and minor agglomerate.

In the vicinity of Beaver Lake the argillite occurs as a breccia with quartz and calcite infilling. Locally the breccia fragments are moderately silicified, suggesting that the area has been subjected to epithermal alteration.

APPENDIX I

Statement of Qualifications

STATEMENT OF QUALIFICATIONS

I, Andrew W. Gourlay, hereby certify that:

1. I am presently employed by MineQuest Exploration Associates Ltd. as Senior Geologist.
2. I am a graduate of the University of British Columbia (B.Sc. Hons., 1977, in geology).
3. I am a Professional Geologist in good standing with the Association of Professional Engineers, Geologists and Geophysicists of Alberta, and an Associate of the Geological Association of Canada.
4. I have practised my profession as geologist for 7 years.
5. The information used in this report is based both on the work of others and on personal execution of the detailed geological mapping.

Signed

A circular professional seal for Andrew W. Gourlay, a Professional Geologist. The seal contains the text "PROFESSIONAL GEOLOGIST" around the top edge, "ANDREW W. GOURLAY" in the center, and "P.R.G." at the bottom. A handwritten signature is written over the seal.
Andrew W. Gourlay

Dated at Vancouver, B.C.
this 7th day of December,
1984
