SUMMARY GEOLOGY (lithology, age, structure, alteration, mineralization, size, and attitude):

The Brent-Oak claims group ~~are~~ is underlain by volcanic rocks of the Myra Formation within the Paleozoic Sicker Group. A 1985 VLF magnetometer and induced polarization survey was conducted to ^{further} delineate conductive zones detected during a 1984 airborne survey. A large east-west trending 550m long chargeability anomaly (open to the east) is flanked by a VLF anomaly to the north. Examination of this geophysical structure is to follow.

INTRODUCTION

Kidd Creek Mines Ltd started exploration of the Esso Mineral's BRENT 1, OAK 1 - 3 claim group in mid April of 1985. Kidd Creek had reached a joint venture agreement with Esso in 1984. The claims are located in the Victoria Mining District. The nearest centre is the town of Chemainus. This report will deal only with the work done between April 20 and May 12, 1985.

The exploration program consisted of line cutting, with subsequent induced polarization, horizontal loop electromagnetic, V.L.F., and magnetic surveys. Line cutting was contracted out to Bill Chase and Associates of White Rock, B.C. For the period ending May 12, 1985, 14.61 km of grid line were cut and surveyed and 1.23 km of baseline were cut for a total of 15.84 km. Geophysical surveys were conducted by Kidd Creek personnel. These surveys were aimed at detecting Cu, Zn, Ag, Au mineralization within volcanic rocks of the Myra formation, Sicker group. Airborne electromagnetic surveys flown over the claims in September 1984 indicated that several weakly conductive zones existed. These zones were targets for the 1985 ground geophysics program. These zones may be related to base metal and pyrite mineralization.

EQUIPMENT

- 1 Scintrex I.P.R. 10 Receiver (Time Domain System)
- 1 Scintrex 250 Watt Transmitter (Time Domain System)
- 1 Scintrex I.G.S. 2 VLF/Mag Data Acquisition System
- 1 Scintrex MP3 Magnetometer, Base Station -
(Total Field Proton Magnetometers)
- 1 Apex Parametrics, Maxim 11+ Electromagnetic
System

DATA PRESENTATION

The data is presented in section format where the geophysical profiles are stacked above the topography for each line. The profiles are plotted at 1 to 2500. This format facilitates interpretation.

A compilation plan at a scale of 1 to 10,000 is also included to show the grid location, layout and significant geophysical anomalies.

SURVEY PROCEDURES

Since the weakly conducting zones indicated by the airborne survey generally have a east-west strike a grid of lines, using a common E-W baseline, was

established and oriented to cross the conductors at right angles. Line separation was generally 150 m. Station separation was set at 20 m horizontal. In areas of steep topography portable inclinometers were used to correct for slope. Topography profiles were prepared for all lines. By May 12, 1985 15.84 km had been completed.

The V.L.F. and Magnetic survey were done simultaneously using the new Scintrex I.G.S. II system. The Seattle V.L.F. station, transmitting at 24.8 khz, was used for all the V.L.F. work, since it provided fairly good coupling with east west trending conductors and had good signal strength at our grid location. Three components of the V.L.F. field were read; horizontal field strength, vertical in-phase component and vertical quadrature component. The vertical in-phase component is plotted on the accompanying profiles. Listings of the horizontal field strength and vertical quadrature components are provided at the back of this report (Pocket 4). The sign convention for the vertical in-phase data is as follows; when facing the station a field dipping to your right will be positive.

The magnetic survey was completed with the sensor mounted on a backpack. Accuracy per reading is plus or minus 5 nanotesla. A base station standard of 56,000 nanotesla was assumed for this survey. The base station was run continuously to monitor the diurnal shift of the earth's magnetic field. Both the I.G.S. II and the base station magnetometer were total field microprocessor controlled instruments, capable of performing automatic diurnal corrections and plotting when connected to each

other and a suitable printer. These state of the art instruments proved to be very convenient to use and durable under field conditions. Listings of the total field magnetic data are provided at the back of this report (Pocket 5)

For the Induced Polarization survey the Schlumberger electrode array was chosen. The reasons for using this array are:

- a) simple anomaly shape
- b) good lateral resolution
- c) least affected by topography
- d) better signal-to-noise ratio for a given depth of investigation (important when using a small portable transmitter).
- e) operational ease in rough topography.

Transmitter dipole separation "AB" was fixed at 140 meters horizontal while the receiving dipole separation was fixed at 20 m horizontal. However, slope distance electrode separation varied with the topography. The current dipole (AB) while remaining parallel to, was separated from the receiving dipole (MN) by a few metres. This separation plus the fact we were working in Time Domain avoided or reduced any inductive and/or capacitive coupling problems. In addition, three slices of the decay curve were monitored to ensure the curve shape was normal. Extra effort was made to ensure the electrode contacts with the ground were always well under 50 K ohms. The care taken with the survey, plus strong primary signals

(generally greater than 50 mv) ensured data accuracy to be within one millisecond. The survey tested the 10 to 70 metre depth with prime emphasis on the upper 30 metres. A curve showing the typical depths of investigation characteristics for the array (assuming homogeneous ground) is included as Appendix C.

For the horizontal coplanar loop electromagnetic work the Maxmin II+ system was used. Coil, separation of 120 m or 200 m were used in conjunction with the frequencies of 3555 HZ and 888 Hz. The highest frequencies were used since they are more capable of detecting weak conductors. Slope corrections were applied to the in-phase data to compensate for coil separation variation. These corrections were calculated from the topography profiles.

DISCUSSION OF THE RESULTS

The geophysical surveys have generally indicated that overburden thickness is in the five metre range, however, there are indications that the overburden becomes thicker to the west. Line 13W may have 10 to 15 metres of overburden.

The chargeability results indicate the sulphide content of the bedrock is generally less than one percent, however anomalous chargeability values were recorded in two areas.

The large, moderate strength chargeability anomaly, centered around 12+40 South on line 1+50W is significant. This zone is on strike with the old Sharon copper showing located on line 1+50E at 13+00S. In general, this complex anomaly is probably due to 2% to 3% disseminated sulphides, however, it is likely that some narrow zones exist within which the sulphide content may exceed 20%.

A second much smaller, moderate strength chargeability anomaly was recorded over the northern end of the old Quarry on line 6+00W at 14+60S. Pyrite exposed in the Quarry is undoubtedly the source of this anomaly.

A V.L.F. anomaly flanks the north side of the I.P. anomalies. Generally there is a fair correlation between the stronger chargeability and V.L.F. responses, although there are some weak V.L.F. anomalies with no appreciable correlating chargeability response. These responses are due to something other than sulphides, perhaps a water filled shear or a weakly conducting sediment.

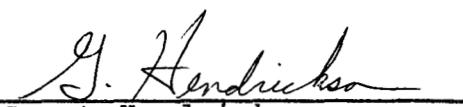

An interesting thin linear magnetic anomaly, centered around 2+50W and 10+75S has been detected. This anomaly may be related to oxide iron formation. Although numerous occurrences of Gabbro exist within the grid, they generally are not well revealed by the magnetic survey. The magnetic anomalies at the north and south end of lines 1+50E may however be related to Gabbro.

The horizontal loop electromagnetic survey was limited. This technique is not effective in exploring zones of weak conductivity due to the relatively low frequencies employed by these systems. It is interesting to note, however, the modest quadrature anomaly associated with the main chargeability response, near 1200S on line 1+50W.

CONCLUSION

The main I.P. anomaly centered around 12+40S on line 1+50W deserves further work. A program of trenching and drilling could quickly evaluate the centre of this anomaly. In addition, the narrow flanking I.P./V.L.F. anomaly on the north side of the main chargeability anomaly should also be tested.

A study of the work done on the old Sharon copper showing by previous operators should be completed. This old showing is related to the above mentioned anomalies.
