## INTRODUCTION

Mineral claims have been staked as part of the Kangaroo prospect since May 25, 1981. The area has a long history of gold prospecting including placer gold mining along Cedar and Spanish Creeks. Lode occurrences on Spanish Mountain have been explored intermittently for many years including the old Mariner showing area presently being explored by Mount Calvary. This occurrence, 4 km west, and the discovery in 1983 by Eureka Resources - Amoco at Frasergold creek some 60 km southeast, both occur within upper Triassic black phyllites and has caused intensive exploration within this unit. Previous geologic models on these properties described stratabound controls on mineralization, but more recent detailed mapping at the Mount Calvary property has described an epigenetic model at mineralization with better gold grades (>.1 oz/t Au) occurring in specific strata in areas of abundant quartz veins.

Of several geochemical targets examined by work described in this report, the one occurring in the north part of the property is very similar in geological setting to the Mount Calvary property and is the most promising target for further exploration. Best results from trenching yielded .007 oz/t Au over 20 m collected within black phyllites in an area with no quartz veins. This and other geochemically anomalous zones could be fringe mineralization to areas of better grade mineralization masked by thin but persistent till cover. Further trenching is the cheapest and most direct method of evaluating this potential.

The present survey collected 455 soil samples, 33 rock chip samples from individual outcrops and 129 rock chip samples from the four trenches.

## LOCATION AND ACCESS

The property covers much of the east flank of Spanish Mountain between Quesnel Lake in the south and Spanish Lake in the north. It lies about 15 km southeast of the town of Likely, from which point a network of good logging roads leads to the property area. Particularly good secondary road access occurs throughout the main area of interest in the north portion of the claim block.

MINERAL CLAIMS

The property consists of thirteen contiguous LCP claims (204 units) as listed below and shown on Figure 2.

<u>CLAIM NAME</u>	<u>UNITS</u>	<u>RECORD #</u>	<u>RECORD DATE</u>	<u>OWNER</u>

GEOLOGY

The southwestern portion of the claims is underlain by a mixed succession of intermediate to acidic volcano-clastic sediments ranging from coarse lapilli tuffs to argillites of Upper Triassic to Lower Jurassic age. Two areas within this area had exploration targets identified from previous surveys and were examined in more detail by the present survey.

One of these targets was a number of airborne VLF anomalies and coincident weak magnetic highs shown on Figure 1 of a report by J.T. Walker dated July 9, 1984. In this area, shown on Figure 4 in southeastern Kangaroo #3, green andesitic tuffs containing up to one or two percent pyrite have 10 to

20 m thick argillite interbeds that contain up to five percent pyrite. Exposure is fairly good in this area and the weak VLF-EM anomalies might be caused by the strong contrast between the massive andesites and more by highly pyritic argillites.

Another area of interest in the southern portion of the claims occurs east and west of the legal corner post for the Wank #1 - #4 mineral claims. Here andesite and minor argillite have local areas of sulphide-ankerite alteration with some bull quartz that yielded a high of 370 ppb Au in a soil. The small size of these zones and lack of continuity along strike make these targets unworthy of more detailed examination.

The northeastern portion of the claims is principally underlain by foliated and/or metamorphosed rocks of Upper Triassic age and contains the area explored by trenching. A previous soil sample grid was also enlarged in this area.

Stratigraphy of the Upper Triassic rocks has been mapped in some detail and subdivided into four units which form a syncline-anticline overturned to the west. The stratigraphically lowest and probably oldest unit is black phyllite, slate, shale and argillite with minor limy sections. Wispy quartzose segregations occur in several outcrops and ankerite porphyroblasts up to 0.5 cm diameter form up to 30 percent of rock volume but more typically form less than five percent of rock volume. A few beds of ankerite less than 1 m thick were noted along a road in the western part of the survey area. (Figure 5). The unit is uniformly black to dark grey without any or only a minor volcanic component. Although only the top of the unit is mapped, it is very extensive, underlying much of the area to the northwest and southeast, based on a few reconnaissance traverses.

The black phyllite unit grades upwards into mixed andesite tuffs and tuffaceous argillite. Sections of black phyllite, slate, shale and argillite appear interbedded with tuffaceous sections particularly near the base of the unit. One of the commonest and most striking tuffaceous rock types, particularly higher in the unit, is comprised of multiple tuff beds 2 cm - 6 cm thick with shaly segregations less than 1/2 cm thick. Other more massive argillaceous tuffs also occur throughout the section. This unit appears to be approximately 200 m thick, thickening to 500 m at major fold axes.

Conformably "overlying" the andesite tuff unit is a coarser andesite unit grading from breccia and pillow breccia at the base to pillow lavas higher in the section. The pillows and pillow breccias show 2 cm thick cooling rhinds and variolitic cores but have been deformed somewhat by folding, faulting and regional metamorphism. Some massive fine grained diorite sections are thought to be flows but may be small dykes, sills or plugs. The unit is exposed only in the core of a major syncline without any overlying strata. Thus the thickness is unknown but is at least 100 m thick at this location.

The only other unit mapped by the present survey is a massive, blocky, clean, uniformly pale-grey dacite to andesite tuff with barely discernable bedding. Its age relationship to the other units is uncertain but its distribution suggests it might underlie or occur within the black phyllite unit.

The black phyllite and argillaceous tuff units commonly contain pyrite cube impressions up to 2 cm diameter with rims of quartz less than 2 mm thick. Pyrite is generally not present in the cubic impressions having been removed by weathering or alteration. Silica flooding of the matrix is generally present locally to a minor degree in areas of more intense occurrence of quartz rimmed pyrite cube impressions. The pyrite impressions occur as lenses along bedding up to one or two cm thick and also as lenses along fractures crosscutting bedding. Pyrite mineralization greater than one or two percent is not common but does occur in outcrops along a main creek at R797 to R806, at R639, at R686 to R690, at R692 to R703, and locally along the road cuts and better exposures in the large +20 ppb Au soil anomaly on Figure 5. Quartz veins were only abundant in the creek northwest of Trench #4.

The pillow breccia to pillow andesite unit is variably altered to epidote often quite intensely and in several outcrops cut by zones of intense quartz vein lacework with associated ankerite and sercite.

Structural interpretation from a previous assessment report by G. Richards dated November 20, 1984 described a major syncline overturned to the west.

The northeastern portion of the claims were examined for mineral potential by extending the grid-controlled soil sampling survey described in the previous report and by trenching two areas underlain by black phyllites with anomalous soil and rock chip gold geochemistry.

#### GEOCHEMISTRY

Geochemical sampling was done to provide more detailed examination of the three areas described above; two in the southwestern portion of the claims and one large area in the northeastern portion of the claims.

Soils, silts and rock chips were collected along survey lines and along roads and creeks tied to baselines and topographic features. Soil samples were collected from pits dug with a mattock to a depth of approximately 20 cm. B-horizon soil was collected from the pit using a stainless steel scoop and placed in an identified, gussetted, kraft paper sample bag. Silts samples were collected from active silts using a stainless steel scoop. Rock chip samples consist of from three to ten rock chips small enough to fit into the gussetted kraft paper sample bags used for all samples.

All samples were shipped to Chemex Labs Ltd., 212 Brooksbank Avenue, North Vancouver, B.C. for geochemical analysis. All samples were analyzed for gold, using a fire assay preconcentration with atomic absorption analysis.

Results from the two southeastern areas examined contained only a few anomalous samples. No further work is warranted in these areas.

Four trenches were dug in black phyllites in the northeastern portion of the claims. Results are provided in an Appendix. Trench #1 was sampled from the southwest to northeast using 2 m intervals numbered WL110 to WL170. Four test pits, WL171-174, were dug on the road corner some 50 m further east and Trench #2, WL175-178, occurs 100 m north. Trench #3 was sampled from north to south, also with 2 m intervals numbered WL179 to 228. Trench #4 was sampled from north to south using 5 m samples numbered WL230 to 235, 10 m samples numbered WL236 and 237, and an 18 m sample numbered WL238.

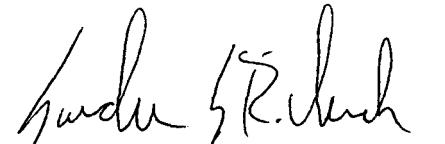

All trench results were well below ore grade. Refer to Appendix II. The best interval occurred in Trench #3 from WL219 to WL228 at the extreme north end of this trench. This interval represents 20 m of .007 oz Au/t.

Results of soil sampling from the northeastern area examined did not appreciably change the anomalous gold patterns described in the November 20, 1984 report. Extensive, although not necessarily deep, glacial till lies adjacent to some of these anomalous gold patterns and offers cover-play targets for further exploration. Referring to Figure 5, there are two such areas; one lying between and south and east of Trench #1 and #3, and the other area lying northwest of Trench #4 beyond the big creek and south and east of Trench #4 as far as R639 and R641. Intervening soil samples in this last area are tills and their low gold values should be ignored in evaluating this area.

#### CONCLUSIONS AND RECOMMENDATIONS

Recent work has evaluated three areas within the claim block: a cluster of low order VLF-EM anomalies coincident with a low order magnetic high; an area of spotty anomalous gold in soils in the southwestern part of the property; and a number of anomalous gold zones underlain by black phyllites in the northeastern part of the property. This last area is similar in geological setting to the Mount Calvary property 4 km west and is the best target for further exploration. Limited trenching was carried out in two areas of strong gold geochemistry with the best results being 20 m of .007 oz Au/t over the extreme north end of Trench #3. Further exploration should consider additional trenching around both areas trenched.

Respectfully submitted,

Gordon G. Richards, P.Eng.

STATEMENT OF QUALIFICATIONS

I, Gordon G. Richards, of Richmond, British Columbia, do hereby certify that:

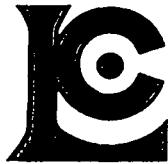

1. I am a Professional Engineer of the Province of British Columbia, residing at 5700 Forsythe Crescent, Richmond, B.C., V7C 2C3.
2. I am a graduate of the University of British Columbia, B.A.Sc., 1968, M.A.Sc. 1974.
3. I have practised my profession as a mining exploration geologist since 1968.
4. This report is based on my personal knowledge of the district, and mapping of the geology at the property.

A handwritten signature in black ink, appearing to read "Gordon G. Richards".

Gordon G. Richards, P.Eng.

#### LEGEND

RJa - Basaltic tuff & breccia; argillite, flows, chert

uRal - Phyllite, argillite, minor greenstone  
(sub-greenschist to amphibolite facies of metamorphism)

uRa3 - Greenstone, tuff breccia, argillite  
(may include undivided uRal)
