1. INTRODUCTION

1.1 Location and Access (Figures 1 & 2)

The Morning Toad claim group is located on Toad Mountain, seven kilometres south west of Nelson in the Nelson Mining Division, B.C.

Directions:

From Highway 6, turn up the Giveout Creek Forestry Road and continue until crossing Give-out Creek. The four-wheel drive road on the uphill side is the old Silver King Mine road. Continue up this road until crossing the West Branch of Give-out Creek. The skid trail leading up the creek continues to the showings on the ridge.

One-way travel time is 40 minutes from Nelson by truck and another 40 minutes walking up to the showings.

Alternatively, an Okanagan helicopter is permanently based in Nelson and can provide quick access directly to the ridge.

1.2 Claims and Ownership (Figure 3)

The property consists of twelve claims and two crown-granted claims. Claim data is as follows:

| Name: | Record No.: | Units: | Record Date: | Registered Owner: |
|------------------|-------------|--------|---------------|-------------------|
| A.G. | 4248 | 1 | Oct 9, 1985 | L. Addie |
| A.G. 1-6 | 3829-3834 | 6 | July 27, 1984 | L. Addie |
| Whiskers 1-5 | 3926-3940 | 5 | Oct 9, 1984 | R. Palmer |
| Black Witch c.g. | L. 199 | 1 | | R. Palmer |
| Tough Nut c.g. | L. 4146 | 1 | | R. Palmer |

1.3 Physiography and Vegetation

The elevation of the property varies from 1500 to 2000 meters. Glacial erosion has rounded the ridges and the lower slopes have accumulations of glacial drift. The relief is moderate to steep. Outcrop is limited to small bluffs and outcrops on steeper slopes, the ridge, and in the stream gullies. Soil horizons are generally well developed, with the depth to bedrock less than one meter near the ridge. The snow-free season is June to October.

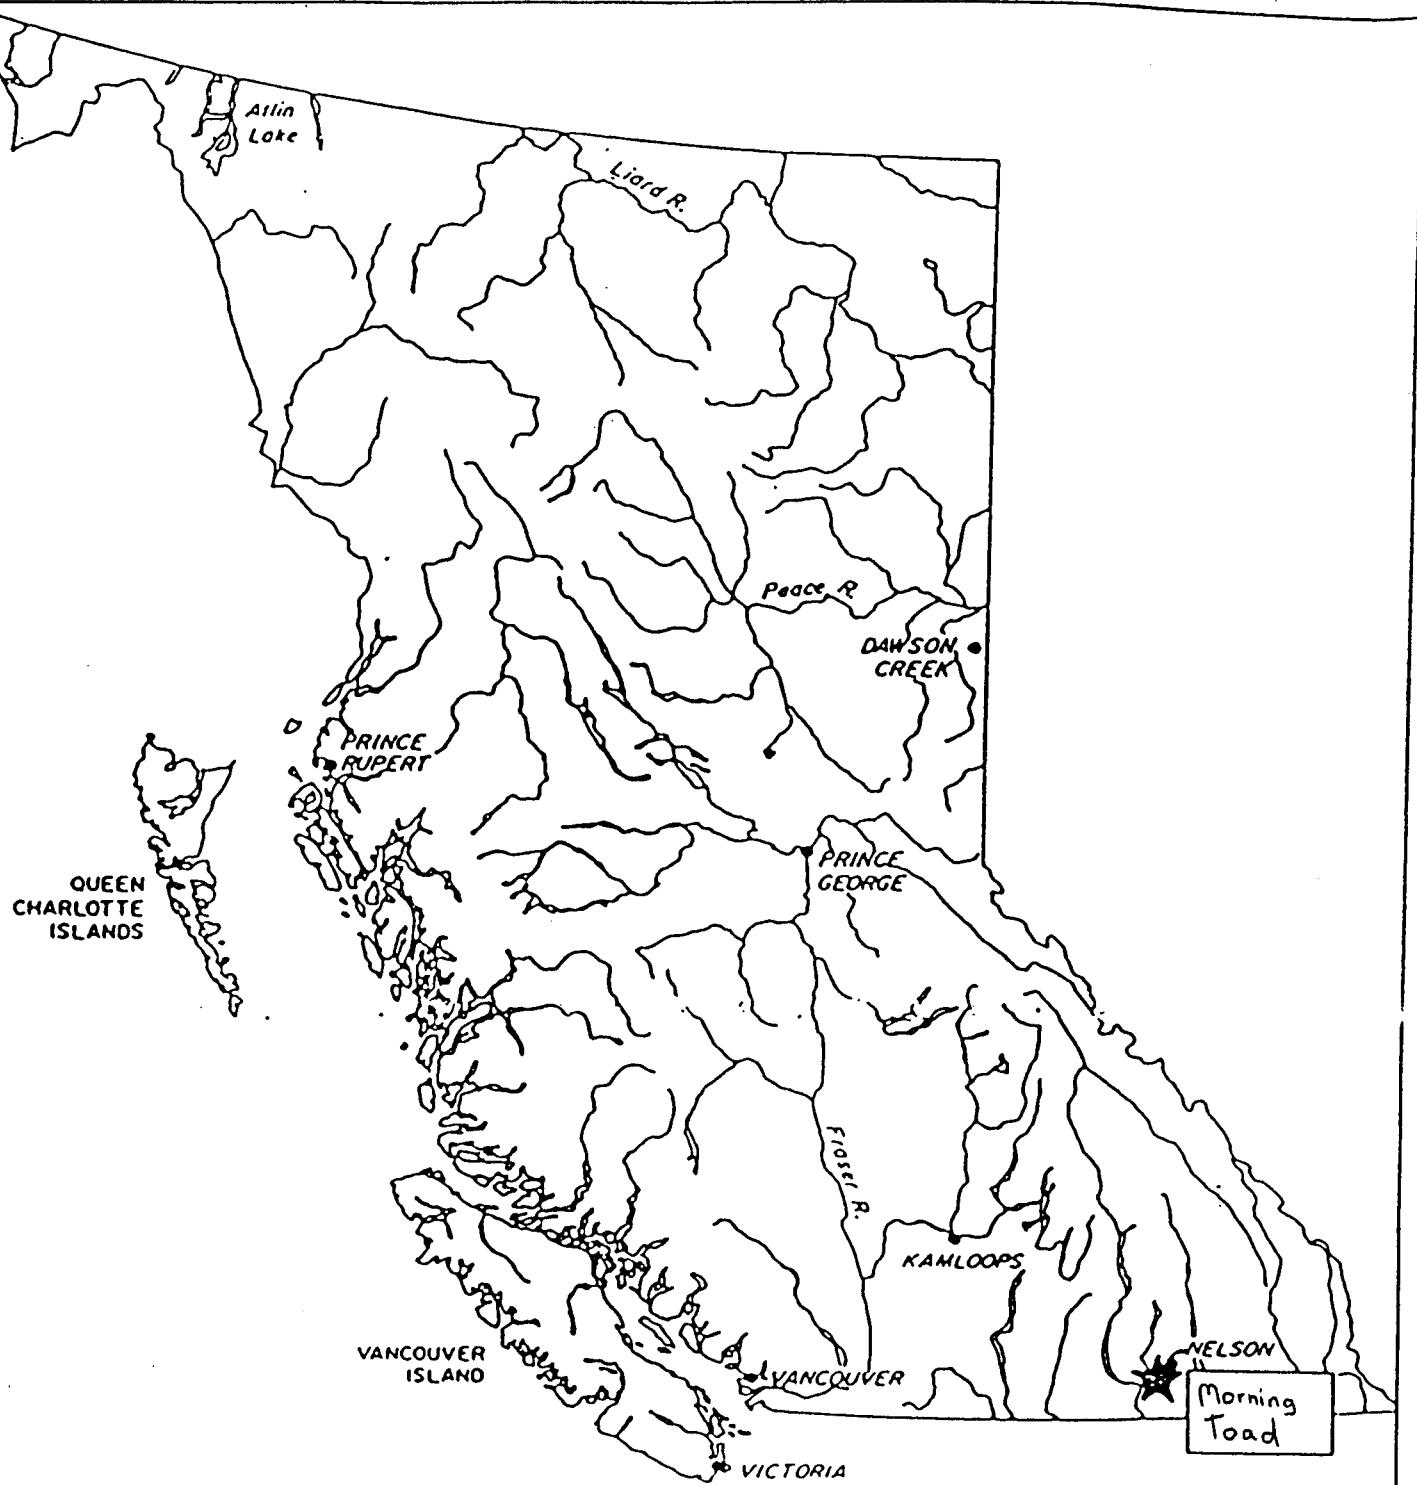

Figure 1. Location Map

Morning Toad Claim Group

MILES
50 0 100 200

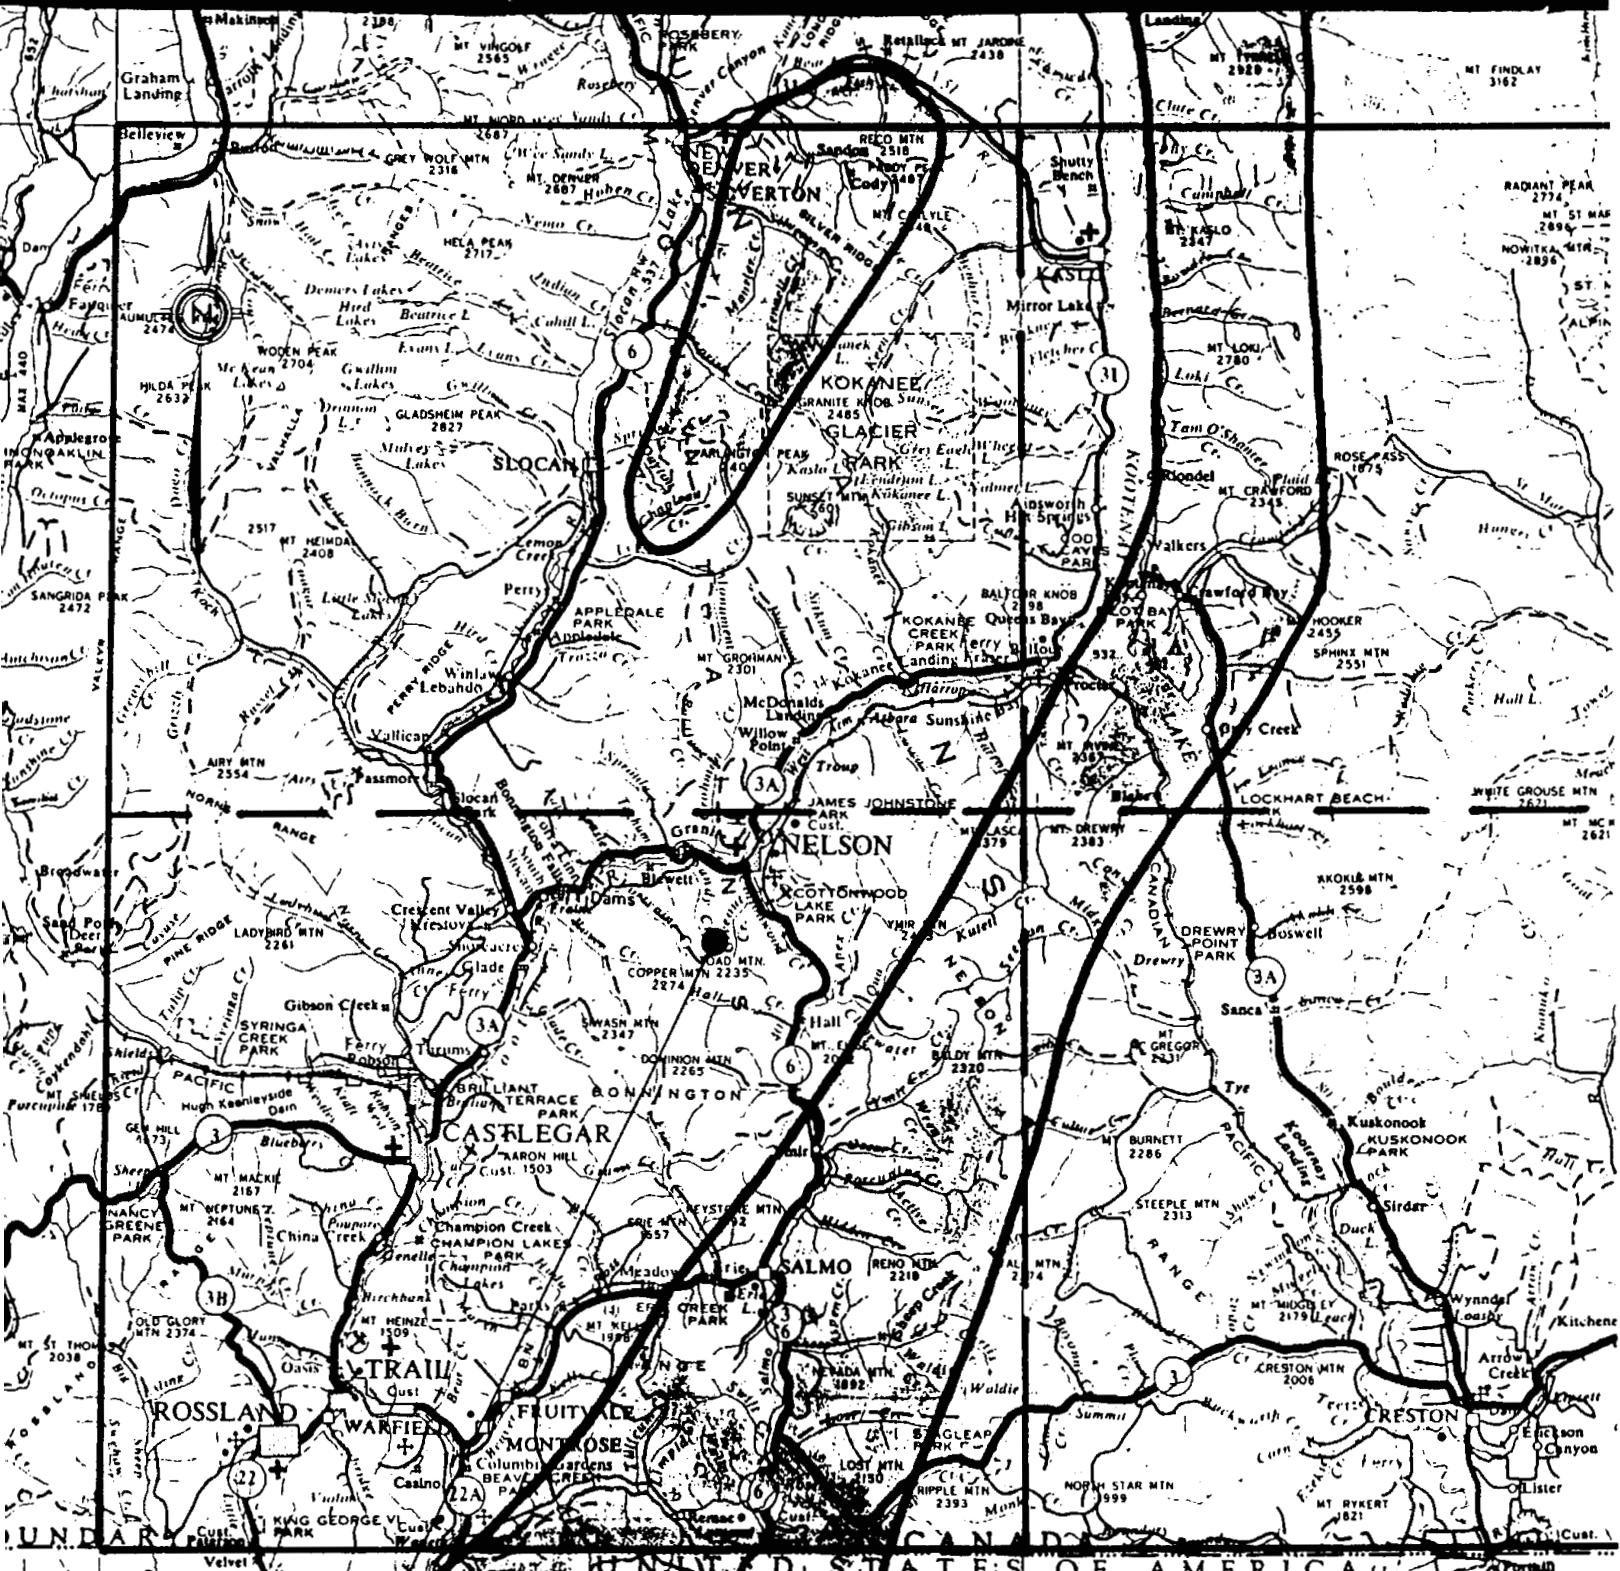

Figure 2. Detailed Location Map (1:250,000 scale)

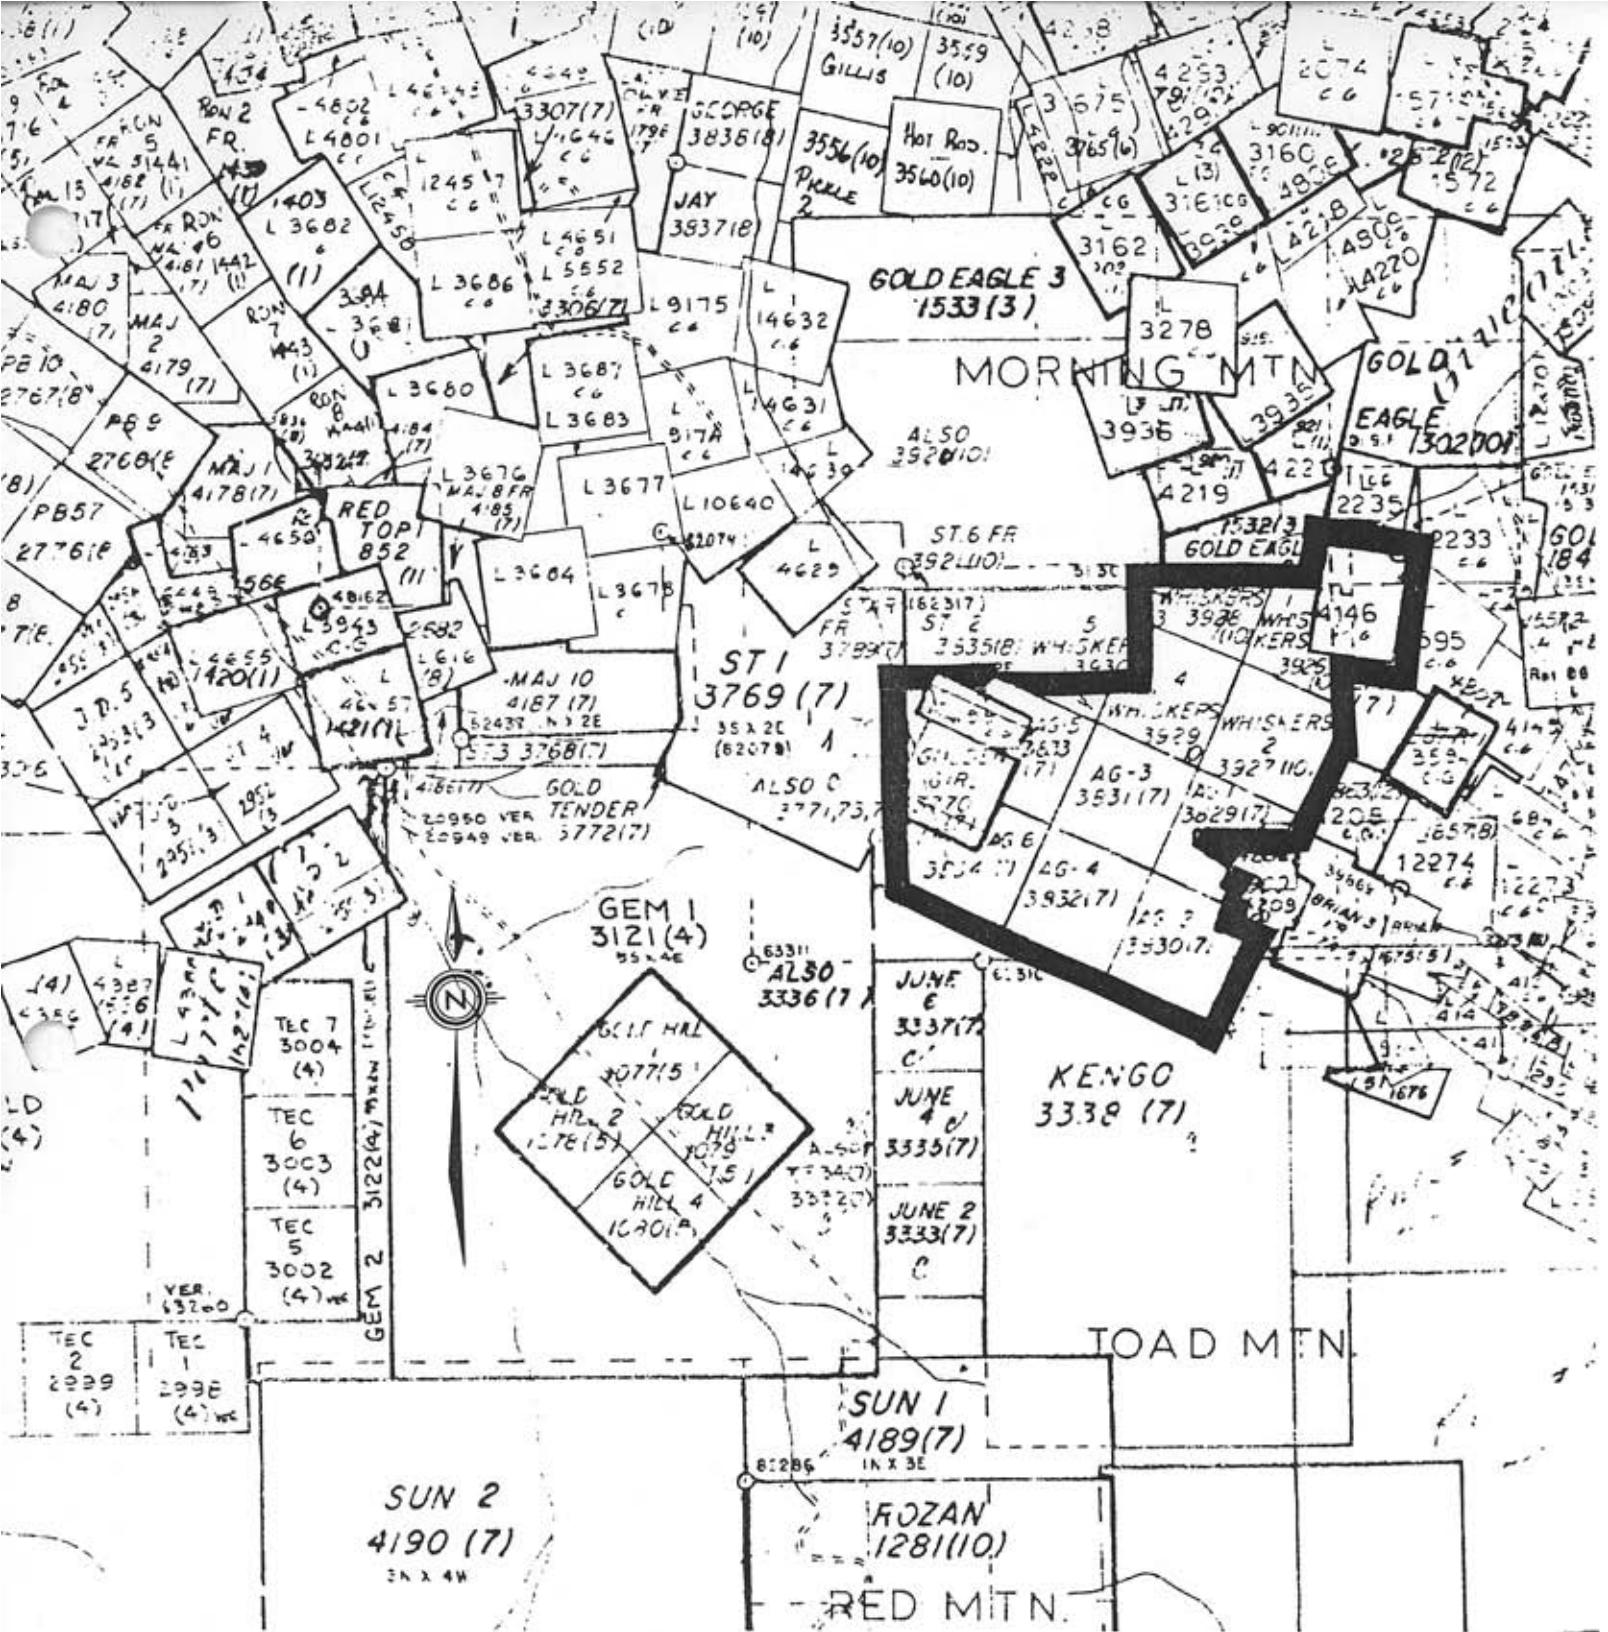

Figure 3. Morning Toad Claim Group.

Vegetation is second growth conifers with moderate undergrowth. Heavy "buckbrush" and Devil's Club grow in stream valleys and on saturated slopes.

1.4 Past Work

Prospecting in the area commenced in 1880 and by 1886 the Hall brothers had brought the nearby Silver King mine into production. The 1890-91 G.S.C. Annual Report (p.172s) mentions some of the workings within the present claim group.

On the Sandy Creek slope of the mountain are some important locations, among which are the Toughnut and Evening. On the former a shaft has been sunk 80 feet, and a tunnel run 127 feet. The vein is from four to eight feet wide, and contains ore of a high grade character...A tunnel has been run in the Evening, which is an extension of the Toughnut, a distance of 137 feet, in addition to an incline 65 feet.

The property also contains several shafts, drifts, and inclines for which there is no record.

In 1974, Granby Mining Co. Ltd. drilled three holes totalling 610 feet. Drill results were negative.

1.5 Summary of Present Work

A preliminary exploration programme was carried out over an area of known mineralization. Trail-clearing and placement of a 400x700m grid over the area of interest commenced on August 15, 1985. Soil sampling then resulted in a total of 59 samples being collected at 40m intervals on lines spaced 100m apart. A magnetometer survey was then carried out along the same grid lines, with a station every 5 or 10m. The last day on the property, September 3, 1985, was spent mapping old showings and prospecting. This resulted in the collection of 19 rock samples for analysis, three thin sections, and two lead samples for possible age-dating.

July 25, 1986 was spent resampling a gold anomaly found during the first stage. Sixteen soil samples were collected, along with 11 rock samples, nine of which were from the soil pits.

2. GEOLOGY

2.1 Regional Geology (Figure 4)

The Morning Toad claims are within the Elise Formation of the Rossland Group. The rocks are lower Jurassic marine volcanics with minor interbedded sediments. The formation is mainly comprised of andesite and basalt, metamorphosed to greenschist facies. Agglomerates, flow breccia, tuff, minor shales and siltstones also occur. The top of the formation is interbedded with soft carbonaceous sediments of the Hall Formation. The thickness of the unit is from 1000 to 2750m.(Little, 1985)

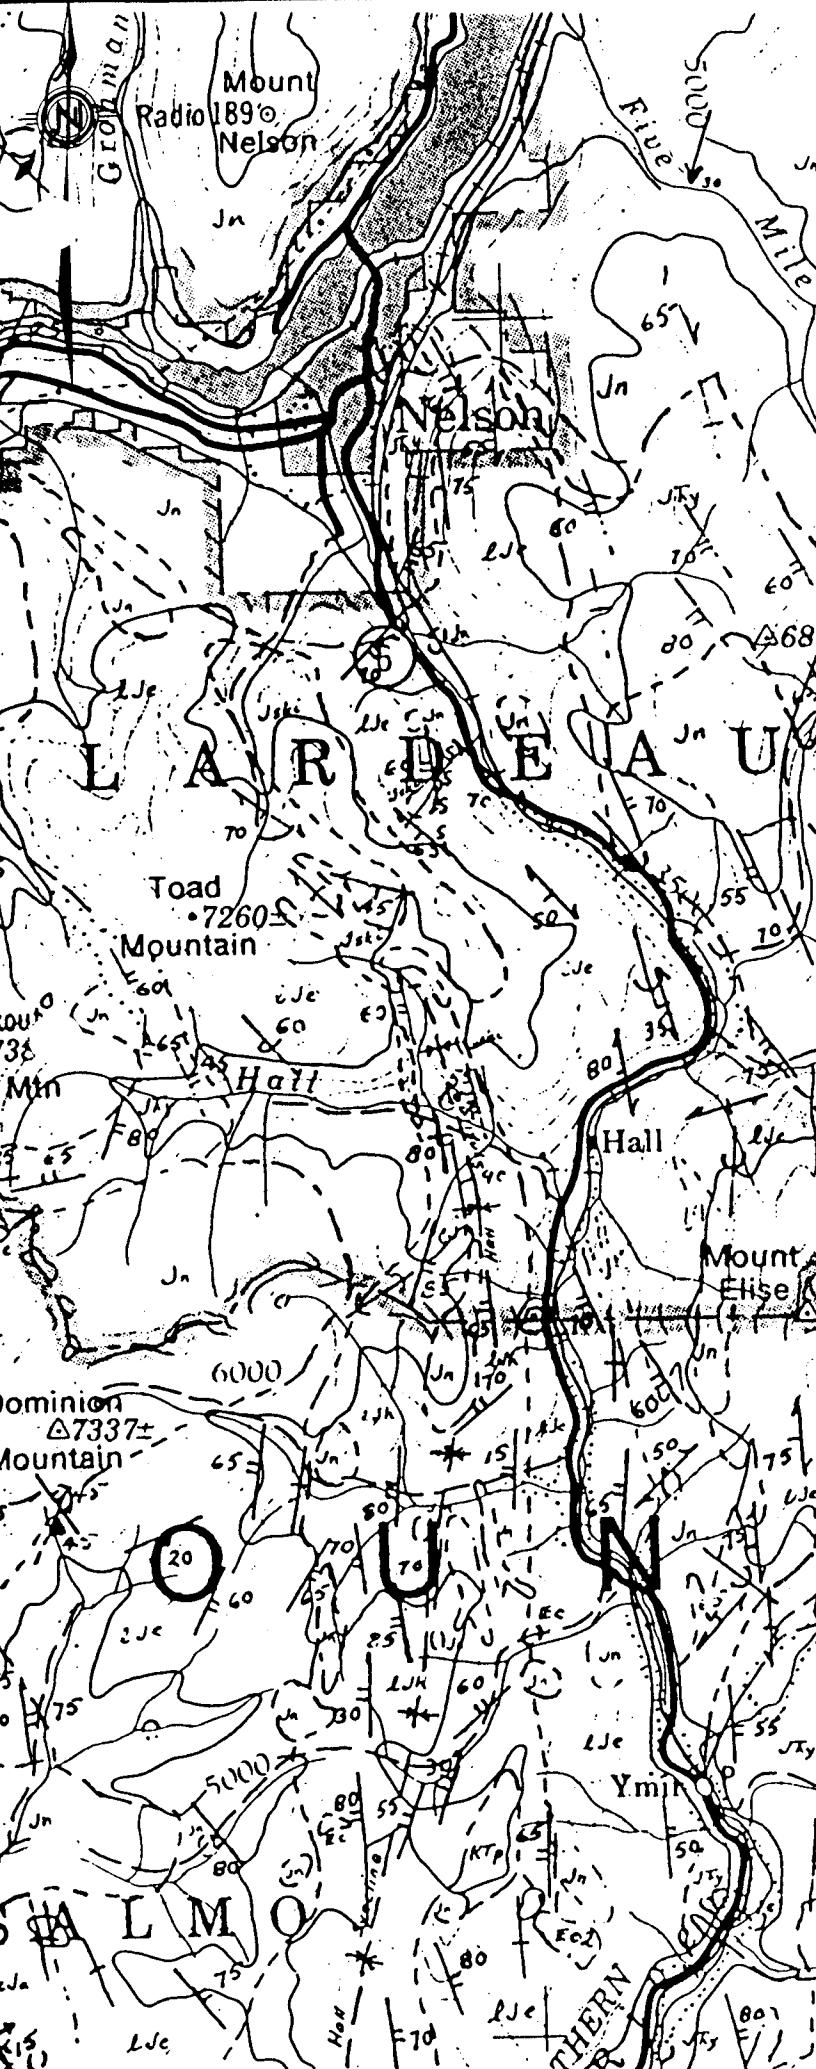

Intrusions proximal to the property have been mapped as pre-Nelson (Batholith) to early Nelson. The intrusion to the west of the property is mapped as a pseudo-diorite (formed by melting of the country rock).

2.2 Property Geology (Figure 5)

The volcanics on the property are dominantly augite porphyry flows that have been moderately to pervasively altered to greenschist facies metavolcanics. Minor tuffs and interbedded sediments have previously been mapped in drill core.

Pervasive shearing trend parallel to stratigraphy (Bearing 116°) and mineralization.

Some shears are mineralized and they contain variable amounts of the following minerals: gold, silver, tetrahedrite, galena, chalopyrite, pyrite, sphalerite and pyrolusite in a quartz-carbonate gangue. Sulphide mineralogy varies between shears and the dominant base and precious metals sometimes vary within a specific shear. In addition, mineralization appears to be proximal to a previously unmapped intrusion. This intrusion is sheared, bleached in appearance and pervasively altered. It is interpreted as a shallow level intrusion related to the Nelson batholith.

3. GOECHEMISTRY

3.1 Soil Geochemistry

3.1.1 Sampling Procedures

Soils: "B" soil horizon was collected by digging a 15 to 25cm deep hole with a mattock. Roots and rock fragments were removed and the soil was bagged in kraft paper soil bags. Samples were dried at room temperature and sent to the U.S. Borax assay lab in California, U.S.A.

3.1.2 Determination of Anomalous Values

Anomalous values for Gold, Lead and Zinc were determined by calculating the mean, one and two standard deviations. Values were calculated for both normal and log-normal sample populations. Histograms were plotted and from the histograms a log-normal population was assumed. (Comparisons with values calculated for adjacent properties suggest that the entire grid area is anomalous with regard to gold.)

3.1.3 Discussion of Results - Preliminary

3.1.3a Gold, Silver (Gold - Figure 6a,6b)

Gold values varied from <.02 to 0.39 p.p.m. The calculated mean is .102 with a standard deviation of .82. The strongest anomaly occurs at 4+00E,0+40N and 5+00E,0+40N. It has a coincident mag anomaly.

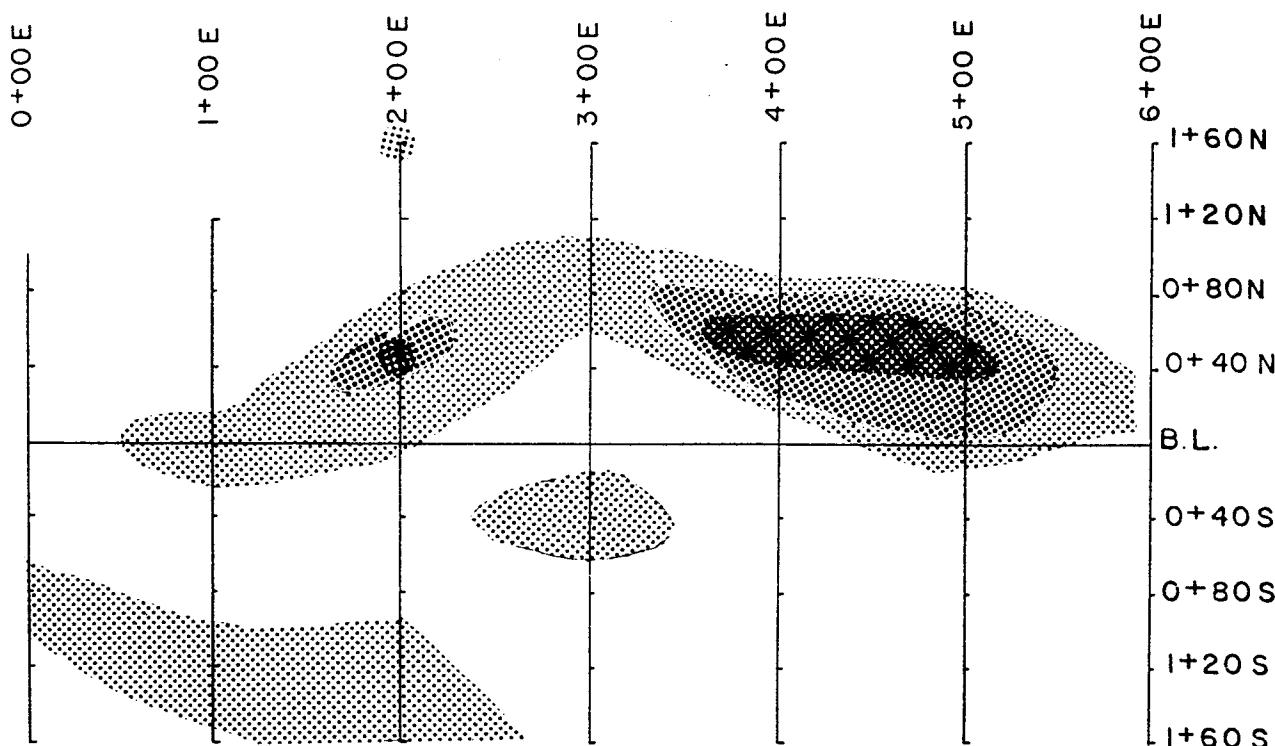

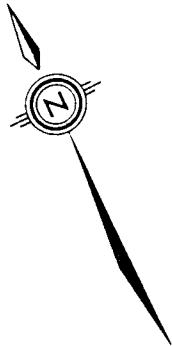

Silver values were not anomalous.

3.1.3b Lead - Zinc (Figures 6c,6d)

Lead values vary from 22 to 226 p.p.m. The mean value is 53.3 and one standard deviation is +39.65. The strongest anomaly is coincident with the Toughnut workings. The soil is contaminated by these early workings.

Zinc values vary from 98 to 1670 p.p.m. The mean value is 246 p.p.m. and one standard deviation is +215. The strongest anomaly is coincident with the Toughnut workings. The soil is contaminated by these early workings.

Note the coincidence of the lead and zinc anomalies (correlation coefficient .815). The strong correlation is also evident in the rock values collected from old workings. Note too that the gold anomaly appears to be independent of the known Cu-Pb-Zn mineralization of the area.

DRAWING NUMBER
Figure 6d.

3.1.3c Mercury

Although the mercury values are anomalous there does not appear to be a strong correlation with zinc. A mercury-zinc correlation was expected as a result of a strong correlation in the rock geochem samples. Also, downhill dispersion does not appear to explain the variation in anomalies. The strongest anomaly is in the vicinity of the Toughnut workings.

3.1.3d Antimony

Antimony values in soil were not anomalous.

3.1.4 Follow-Up Results

The gold anomaly at 0+40N, 4+00E to 5+00E was resampled at 10m intervals along lines 4E and 5E. In addition, a line of samples was collected at 4+50E. These follow-up samples were run for Gold +30 Element I.C.P. at Acme Analytical Labs in Vancouver. Values over 500 p.p.b gold were reported in each of the three lines. The highest value in soil is 810 p.p.b.

3.2 Rock Geochemistry (Figure 7)

3.2.1 Sampling Procedures - Preliminary

Samples were hand-picked from the old workings. Thirteen samples were sent to U.S. Borax assay lab in California, U.S.A. and run for Gold, Silver, Copper, Lead, Zinc and Mercury. In addition, three samples were sent to Chemex Labs in Vancouver and run for Gold, Arsenic, Mercury and 30 element I.C.P. One of these samples was subsequently run at Chemex for Tellurium and Germanium.

3.2.2 Determination of Anomalous Values (See Table 1 - Rock Correlation Co-efficients)

Normal and log-normal histograms were constructed to determine population type. A better fit from log-normal histograms was apparent so a log-normal distribution was assumed. Correlation co-efficients were then calculated between all pairs of the following elements: Au, Ag, Cu, Pb, Zn, Hg.

3.2.3 Discussion of Results - Preliminary

Despite the small sample size (17) certain relationships are worth noting:

Hg-Zn (+.865) The mercury-zinc relationship is a common one but had not previously been noted in this area.

Au-Pb (+.636), Ag-Pb (+.696) The suggestion here is that gold and silver values may be more closely linked to galena than with sphalerite or chalcopyrite in the polymetallic mineralization.

This association may vary on strike (it does at the Silver King mine).

TABLE 1 - ROCK CORRELATION CO-EFFICIENTS

| | Au | Ag | Hg | Cu | Pb |
|----|------|------|------|------|------|
| Au | - | | | | |
| Ag | .611 | - | | | |
| Hg | .488 | .692 | - | | |
| Cu | .613 | .523 | .583 | - | |
| Pb | .636 | .696 | .765 | .348 | - |
| Zn | .582 | .537 | .865 | .65 | .667 |

Population: 17
Degrees of Freedom: 15
95% Confidence limit = 0.482
99% Confidence limit = 0.606

3.2.4 Sampling Procedures - Follow-Up

Where possible, a bedrock or subcrop sample was collected at the base of the follow-up soil pits. These samples were run for Gold and 30 element I.C.P. at Acme Analytical Labs in Vancouver, B.C.

Results of up to 6450 p.p.b. Gold (0.191oz/ton) were reported from the follow-up sampling.

4. GEOPHYSICS

4.1 Proton Magnetometer - Type and Procedure

A Geometrics G-836 proton magnetometer (10 gamma resolution) was used on this property.

Each morning the magnetometer was placed on a fixed point on the grid (a flagged stump) and a measurement would be taken. This would be compared to the value from the first day, and, if different, the correction required to return it to its original value would be noted. The first day stations were measured along the base line on the way down the hill and again on the way back up. The mag line was then closed (within one hour) by remeasuring the stump. As there was no diurnal variation and no variation in the duplicate readings these points became valid stations to tie into. On subsequent days diurnal variation remained low (-30 gammas). These diurnal variations were corrected by dividing the variations into the time between closures. This variation per minute was then calculated for each 10 or 20m station in that loop. These variations were insignificant when data was plotted. Values were drawn as line-profiles rather than as contoured data for the following reasons.

1. The 10:1 elongation of line spacing to station spacing cannot fairly be contoured without losing even slightly oblique structures.
2. The signature of structures can be identified more readily, especially if they are oblique to the grid.
3. The decrease both in average value and attenuation of anomalies becomes apparent as you go down hill (towards L0 + 00E).

4.2 Results and Discussion (Figure 8)

Variations of up to 4500 gammas were measured. The mag seems to pick up the shears very well. Luckily, the gold anomaly identified in the preliminary sampling appears to be coincident with a strong mag anomaly.

5. CONCLUSIONS

A previously unrecognized gold anomaly has been identified in an area with numerous old workings. This gold anomaly has a coincident mag. anomaly which should enable rapid tracing of the structure on strike. Resampling of the anomaly has confirmed +500 p.p.b. soil values over the entire strike length that was rechecked (100m).

Magnetometer lines should have been run at a 50m spacing. Sample stations should be no more than 10m.

6. RECOMMENDATIONS

Extend the grid over the entire property at 100m line spacings.

Sample soils at 20m stations for 30 element I.C.P. and geochem. gold.

Run mag. at 10m stations and profile the data.

Map geology, paying particular attention to foliation direction, amount of shearing, original lithology (if recognizable), cross-cutting structures and mineralization.

The property should be looked at for the following types of mineralization.

1. It has the same style of mineralization as the Silver King mine and is on strike.
2. A previously unmapped intrusion is proximal to the new gold anomaly identified.
3. Extensions of auriferous pyritic schists should be checked in the vicinity of the Black Witch c.g.

7.

APPENDICES

APPENDIX A

Statement of Qualifications

I, GORDON ALEXANDER ADDIE, state that:

1. I am a Geologist residing at #D-806, 1600 Beach Avenue, Vancouver, British Columbia.
2. I received a B.Sc. (Geology) from the University of British Columbia in May, 1986.
3. I am a student member of the Geological Association of Canada and the Canadian Institute of Mining and Metallurgy.
4. I have eight years of geochemical and geophysical exploration experience (seasonal).
5. The findings of this report are derived from data as acknowledged and from personal examinations of this property between August, 1985 and July, 1986.

U.S. BORAX

Geochemical Analysis of Cu, Pb, Zn & Ag* & Mo

Sample preparation

Soil samples are dried at 75°C and sieved to -80 mesh.

Rock samples are ground to -100 mesh.

Digestion

A .50 gram sample is digested with dilute aqua regia in boiling water bath and diluted to 10 mls with demineralized water.

Determination

All the above elements are determined by Atomic Absorption from the solution.

* With background correction.

Geochemical Analysis of Au

Digestion and extraction

A 10 gram sample which has been ignited over night at 600°C is digested hot with dilute aqua regia, and the clear solution is extracted with Methyl Isobutyl Ketone.

Determination

Au is determined by AA from the MIBK extractant with background correction.

Geochemical Analysis of Ba

A .100 gram sample is digested hot with NaOH and EDTA solution. The solution is analysis for Ba by Flame Emission.
