....

LOCATION AND ACCESS

The claims are approximately centered about 53° 31' north latitude and 127° 10' west longitude, on map sheet 93E, seven kilometers north of the west end of Whitesail Lake. The distance to the nearest rail, power, highway and permanent settlement (of Houston, B.C.), is some 140 air kilometers. Good gravel roads from Houston terminate on Tahtsa Reach, 18 km north of the claims.

Present access is easiest by helicopter from Houston or Smithers.

PHYSIOGRAPHY

The claims cover the area bounded by the confluence of Coles Creek with Troitsa Creek. Topography in Coles Creek is a broad valley (elev. 900) modified by low, northerly elongated hills. Troitsa Creek is deeply incised between moderate elevation (1300m) rounded hills. The eastern portion of the claims rises to 1600m on a rounded mountain, containing the only alpine area on the property. The claims are heavily timbered by mature spruce, balsam and hemlock. Swampy terrain is abundant in the Coles Creek Valley. The claims are mostly free of snow from mid-June to November, although significant snow may fall at anytime after late September.

The area is transitional between the Nechako Plateau and the Hazelton Mountain physiographic subdivision.

....

 \smile

CLAIMS AND OWNERSHIP

The claims are owned jointly by Westrex Development Corp., 860 - 625 Howe St., and Whitecaps Energy Inc., 711 - 475 Howe St., both of Vancouver, B.C.

The Troitsa Group comprises 78 units listed below. The Tad 1 - 8 claims are two-post claims.

Claim	<u>Units</u>	<u>Record No.</u>	<u>Expiry</u>
Hugo	20	5132	May 6, 1985
Whisky	20	5133	May 6, 1985
Tad 1-8	8	5134-41	May 6, 1985
Lefty	12	5320	June 23, 1985
Triple D	18	5321	June 23, 1985

PREVIOUS WORK

In April, 1983, a VLF - EM survey was completed on the eastern portion of the Group to attempt to identify the extension of a set of north-east trending faults that transect the southern flank of the Whitesail Range, known to be directly associated with precious metal mineralization within the Whitesail Range. This work formed the basis of an assessment report filed on the Troitsa Group in 1984.

Regional reconnaissance in 1982, by T. Richards in conjuntion with a grubstake arrangement with Ucex Minerals Ltd., revealed strongly anomalous silts in the eastern portion of the calims, with one silt giving the following anomalous results (in ppm); Cu-643, Zn-155, Ag-1.5, As-2776 and Sb-29.

PRESENT WORK

Present work comprised a VLF - EM and magnetometer survey on the eastern protion of the claims to continue the exploration for the trace of the north-east trending structures, to locate and delineate major structures that define the Coles Creek Valley, and to complete the geophysical cross-section of the claims commenced in 1984.

Two men, Dr. T.A. Richards and B. Holden, spent six days on the property, completing 14.5 line kilometers of VLF - EM and magnetometer survey. The investigation was based from a flycamp by Coles Creek. Snow depth was approximately 2 meters depth during this period.

....

GEOLOGICAL SETTING

The Whitesail area lies along the eastern margin of the Coast Plutonic Complex. Upper Paleozoix metamporphic rocks within the Coast Plutonic Complex represent the oldest rocks known Immediately east of the Coast Plutonic Complex, in the area. Lower Jurassic volcanic and sedimentary rocks of the Hazelton These are overlain by generally epiclastic Group predominate. rocks of the Upper Jurassic Ashman Formation and the Lower Cretaceous Skeena Group, followed by volcanic rocks of the Upper Cretaceous Kasalka Group. The final major rock-forming events in the area were episodes of Tertiary volcanism that deposited the siliceous volcanic rocks of the Ootsa Lake Group and the basalts of the Endako Group. A variety of intrusive rocks outcrop in the area. They range in composition from granite to gabbro and they range in age from Paleozic (?) to Tertiary. The area is cut by major systems of generally northeasterly or northerly trending faults. For detailed geological descriptions see Duffell (1959), Hodder and MacIntyre (1980), Tipper <u>et al</u>. (1979) and Woodsworth (1980).

A resurgent caldera (Tahtsa caldera), at least 20 km in diameter, was mapped about 7 km north of the claims by D.G. MacIntyre. The collapsed caldera centre is occupied by rocks of the Kasalka and Skeena Groups and by a variety of intrusions. Several potentially economic mineral deposits are associated with small granodioritic stocks around the priphery of the caldera, possibly localized at intersections between ring and radial fractures related to caldera development (Hodder and MacInyre, 1980). Recent work by T.A. Richards (1984) and G. Woodsworth (1980) indicates that the caldera extends further south than previously mapped and that a section of the caldera ring fracture zone underlies the Coles property.

GEOLOGY OF CLAIMS

The claims are underlain by volcanic and sedimentary rocks of the Jurassic Hazelton Group, which are cut by dykes and stocks, probably related to the Upper Cretaceous Kasalka Volcanics. During most investigations of the claims, heavy snow cover has prevented any definitive geologic interpretation.

The eastern portion of the claims are underlain by massive bedded lapilli tuffs, feldspar porphyry andesite and red tuffaceous mudtones. Rhyolitic to andesite dykes are known to intrude these volcanics in Troitsa Creek, and on the rounded mountain underlain by the Tad Claims, exposures of pink quartz Monzonite and granite are known. In the eastern portion of the claims, bed rock geology comprises interbedded volcanic siltstone, sandstone, lapilli tuff and flow rocks. Certain sandstone members contain abundant pelecypod an ammonite fauna correlative with species found in the Jurassic Hazelton Group elsewhere in west-central British Columbia. Limited exposures of feldspar porphyry were noted on some of the low hills in the Coles Creek Valley. A prominent mag-high in the eastern part of the grid area is likely a small dioritic plug, common locally in this region of the Whitesail Lake map-area.

No obvious zones of mineralization were noted, albiet overburden and deep snow cover restricted greatly such exploration.

- 8 -

GEOPHYSICAL SURVEY

A Phoenix VLF - 16 EM unit and a magnetometer were used together to run the geophysical survey. Readings were standardized at the beginning and end of each days traverse at the 0+00N, 0+00E station as shown on the grids. Station spacings were at 50 meter intervals. Grid lines were placed by hip-chain and compass. A north-south base line was established in using a 100m nylon chain, to tie in the east-west lines. Snow conditions were excellent for snow-shoe run traverse lines.

Transmitting stations used in the survey were Annapolis at 21.4 KHz on channel F-1 and Seattle at 24.8 KHz on channel F-2. Both stations transmitted continually during the survey. Annopolis station nulled at bearing 100° and Seattle at 150° , giving a 50° separation in readings at each station.

A proton precission magnetometer was used for the magnetic survey. The grid used was as for the VLF survey, with 50 meter stations. Magnetic fluxuations at the 0+00N, 0+00E base station are as follows:

		А.М.	Ρ.Μ.
May	3	57341	57333
May 4	4	57331	57344
May	5	57346	57384
Mav	6	57375	57361

Contours were plotted at 200 gamma intervals (in pocket).

MAGNETOMETER RESULTS

Values obtained from the magnetometer survey range between 56,500 and 59,000 gammas. Contour intervals on the accompanying figure (Magnetic Data; in pocket) where chosen at 200 gammas, with 57,000 gammas chosen as the zero contour.

Contoured data display a marked north-trending alignment, parallel to the local grain of the country. Magnetic highs are represented along both the eastern and western portions of the grid separated by a broad plateau with very little magnetic relief. The eastern belt of highs displays the largest magnetic contrast and is in abrupt contact with lows on both its western and eastern borders.

A single high of 59,436 gammas in this region is in excess of 1,000 gammas above its closest competitor. The western belt of magnetic highs rises progressively off the magnetic plateau from the east, and slopes gently towards the western margin of the grid. Central to this western high are a series of minor magnetic depressions.

VLF - EM RESULTS

Two stations, Annapolis and Seattle were received to deduce conductor anomalies. Data are plotted in the accompanying figure, in the pocket.

Annapolis station nulled at bearing 100°, approximately perpendicular to the morphologic grain of the study area. Results, in general, gave very subdued tilt profiles, with a limited set of cross-overs. Because of the paucity of cross-overs, definitive interpretation of the orientation of conductorswill be suspect. Locus of cross-overs tend to trend in a general northeasterly direction, and are located to the northwest and southwest portions of the grid.

The Seattle station nulled at bearing 150° and gave a complex set of well developed cross-overs. The main locus of crossovers trend in a northerly direction, parallel to the topographic grain of the study area. Cross-overs are concentrated in the eastern and western portions of the grid.

INTERPRETATION OF RESULTS

Magnetometer data and VLF - EM data from the Seattle transmitting station gave coincident patterns that mimic the topographic trend of the Coles Creek Valley. The persistence of northerly-trending cross-overs on the east and west portion of the grind are likely reflecting the trace of fault zones that have been hpothesized to occupy the Coles Creek Valley. A lack of faults in the central portions of the grid is apparent from both the lack of cross-overs and the magnetic plateau that typify this area. Mag-highs in the eastern portion of the grid likely reflect the presence of basic intrusions, probably microdiorite dykes that are common features in this region of the Whitesail Lake map-area. Dykes frequently occupy fault zones. Dyking is a likely phenomenon along the western protion of the grid, as the mag-highs, and VLF cross-overs are coincident with the trend of low, northerly elongate ridges. Magnetic depressions associated with these anomalous zones possibly reflet beaching, alteration and/or oridation associated with shearing.

Interpretation of Annapolis VLF - EM data is less definitive. A north-east trend is apparent along the northwest and southeast parts of the grid. This trend possibly represents crossfaults or tension-gash shears that are related to the main north-south trend outlined by Seattle VLF - EM data, magnetometer data and topography. This northeast trend is correlative with the well developed north-east trending Whitesail fault system that parallels the southern margin of the Whitesail Range. This trend was also strongly developed in the VLF - EM data noted in the 1984 Assessment Report - Troitsa Property, in the eastern portion of the property. Elsewhere in the Whitesail area, significant mineralized and alteration zones are associated with tension-gash shear systems related to major faults.

Field Data

The results below illustrate the need for using two orthogonal stations when the strike of the prospective conductor is not well-known. The dip angle and amplitude data measured using station NLK in Seattle, Washington, show only a very weak anomaly associated with the two conductive sulphide zones at Cavendish, Ontario. The results obtained using Cutler, Maine reveal a more prominent anomaly, but the best response was obtained using Annapolis, Maryland since the station lies almost due south and the transmitted electromagnetic field is thus maximum-coupled with the North-South trending conductors.
