INTRODUCTION

In July of 1985, a program of geophysical and geochemical surveys was carried out on the GOLD claim supplement group by Hawk Mountain Resources for the owners, J. Duane Poliquin of Surrey, B.C., and Eric A. Shaede of Sicamous, B.C. The purpose of the surveys was to test the area for extensions of a mineralized zone exposed by old workings which contain significant precious metal values, and to locate possible new zones that were undetected by the original development. A total of 14.5 line km of grid lines were surveyed by VLF-EM and magnetometer and 93 soil and stream sediment samples were taken to test the resulting geophysical anomalies.

PROPERTY

The GOLD claim supplemental group is located in the south east quadrant of NTS mineral claim sheet 93N/7W (see figure 1). The claim group is comprised of the following contiguous claims.

GOLD 1-4	5975-8 (11)	4 units
RACHEL 1	7140 (7)	12 units
RACHEL 2	7141 (7)	12 units
NOV	6817 (11)	<u>16</u> units
	Total	<u>44</u> units

The GOLD 1-4 two post claims, owned by Eric A. Shaede of Sicamous, B.C., cover the area of previous development known as the "Klawli" showing. These claims are surrounded by the NOV claims, owned by J. Duane Poliquin of Surrey, B.C. The RACHEL 1 and 2 claims are also owned by Mr. Poliquin.

LOCATION AND ACCESS

The GOLD claims are located at the south end of the Omineca Mountain chain approximately 100 km north of Fort St. James (see figure 1). The property is centered at $55^{\circ} 17'$ N latitude and $124^{\circ} 46'$ W longitude on the south bank of an unnamed tributary creek flowing into the lower Klawli River at a point approximately 4 km below its outlet from Klawli Lake (see figure 2). Access to the property is made primarily by helicopter from Fort St. James, although the town of Manson Creek is within 40 km to the north.

TOPOGRAPHY

The GOLD claims are situated at an elevation of 1000 m on the banks of a small creek. The elevation in the area rises to a 1900 m peak at the headwaters of the creek, beyond the eastern boundary of the claim group. To the west, the topography rises slowly out of the main valley of the Klawli River.

The property is poorly drained with many swamps and bogs scattered over the predominantly glacial-alluvial overburden. The "showing creek" flows in a northwesterly direction from its source for over four kilometers, but makes an abrupt turn to the southwest at the showing before it meets the Klawli River. Except for the workings and rare outcrops at the creek's edge, no bedrock is exposed in the area.

Vegetation on the claims is comprised mainly of immature stands of spruce and pine with moderate to heavy underbrush.

GEOLOGY

The regional geology of this part of the province is dominated by sedimentary and volcanic rocks of the Jurassic Takla Group which are intruded by the Jurassic-Cretaceous Omineca Group plutonic complex. The exposed mineralization itself appears to be in a complex shear zone, about 2 metres wide striking northeast in Takla andesites. This zone has been filled with a mineralized quartz carbonate vein system and altered to a talcose "schist". Pyrite, chalcopyrite, and galena are the major metallic/sulphide minerals present and occur as blebs, veinlets, and fracture fillings in the altered hostrock.

EXPLORATION HISTORY

The GOLD property covers a copper-gold showing known alternately as Kohse Copper or Klawli Copper. This showing was located in the early 1920's and optioned to Consolidated Mining and Smelting Company of Canada, who did some minor trenching and sank two shafts. Since that time various companies and individuals have held the property with little or no further development.

Reconnaissance prospecting by Hawk Mountain Resources in 1984 confirmed the presence of anomalous gold values at the showing. Assays up to 0.48 oz/ton with associated silver values of up to 29.22 oz/ton were collected from the old workings and dumps (see figure 3). The relatively small size of the prospect prompted further exploration to further delineate the known mineralization as well as locate possible related structures and systems. A reconnaissance VLF-EM survey indicated an anomalous zone roughly

parallel to the strike of the exposed mineralization, which prompted a more detailed program of geophysical surveys combined with soil and stream geochemical surveys.

SURVEY PROCEDURES

The geophysical portion of the survey included both VLF-EM and magnetometer surveys. A 14.5 line km grid was established using compass and hipchain methods for control. The baseline used pickets for every 50 m station over an 1800 m length with traverse lines every 200 m varying in length from 450 m to 1900 m. A Phoenix VLF-2 model was used to receive signals from the Annapolis Md. transmitter station. The magnetometer data was taken using a flux gate magnetometer.

Standard procedures were used for collection and preparation of the soil and stream sediment samples. These included collection of 72 samples of B-horizon soils at 25 m intervals (where possible) over the VLF anomalies and collection of 21 stream sediment samples at varied spacings along the creek adjacent to the showing. Samples were screened to -80 mesh and analyzed for Cu, Ag, As, and Sb by acid extraction/ICP methods.

RESULTS

(a) Geophysical Survey

Of the two geophysical methods used, the VLF-EM data seems to be the most meaningful (see figure 4). The survey data indicates that two anomalous zones are present crossing the grid system. In

addition there are several "one line" anomalies. The largest anomaly crosses the grid from 800 W to 1000 E, 50 to 250 m south of the baseline. The second anomaly extends from a point 500 m south of the baseline on the 200 E line, bearing N 60 E, to intersect the first anomaly at or near the 1000 E line. Irregularly spaced anomalies also occur, north of the baseline, on the 400 E, 600 E, 800 E, and 800 W lines. The magnetometer data was found to be highly variable and did not appear to have any relation to the VLF results.

(b) Geochemical Survey

The soil geochemistry results over the VLF anomalies showed little or no associated high metal values (see figure 5). This was primarily due to the extremely poor and variable quality of the soil in the area, being, for the most part, organically derived, or glacial in origin.

Cu values ranged from 20 to 360 ppm with only 3 samples containing greater than 200 ppm. Ag values ranged from .1 to .6 ppm, of which 7 samples contained more than .2 ppm. As in the soils ranged from 2 to 16 ppm with 2 samples showing 9 ppm or greater. Finally, Sb values ranged from 2 to 8 ppm with only 3 samples over the 2 ppm background. Stream sediment samples also failed to show any outstanding anomalies in Cu, Ag, As, or Sb, the results all falling within background levels. A very slight increase in Cu (37 to 59 ppm) values in the stream sediments collected above and below the intersection of the largest VLF anomaly in the stream was observed.

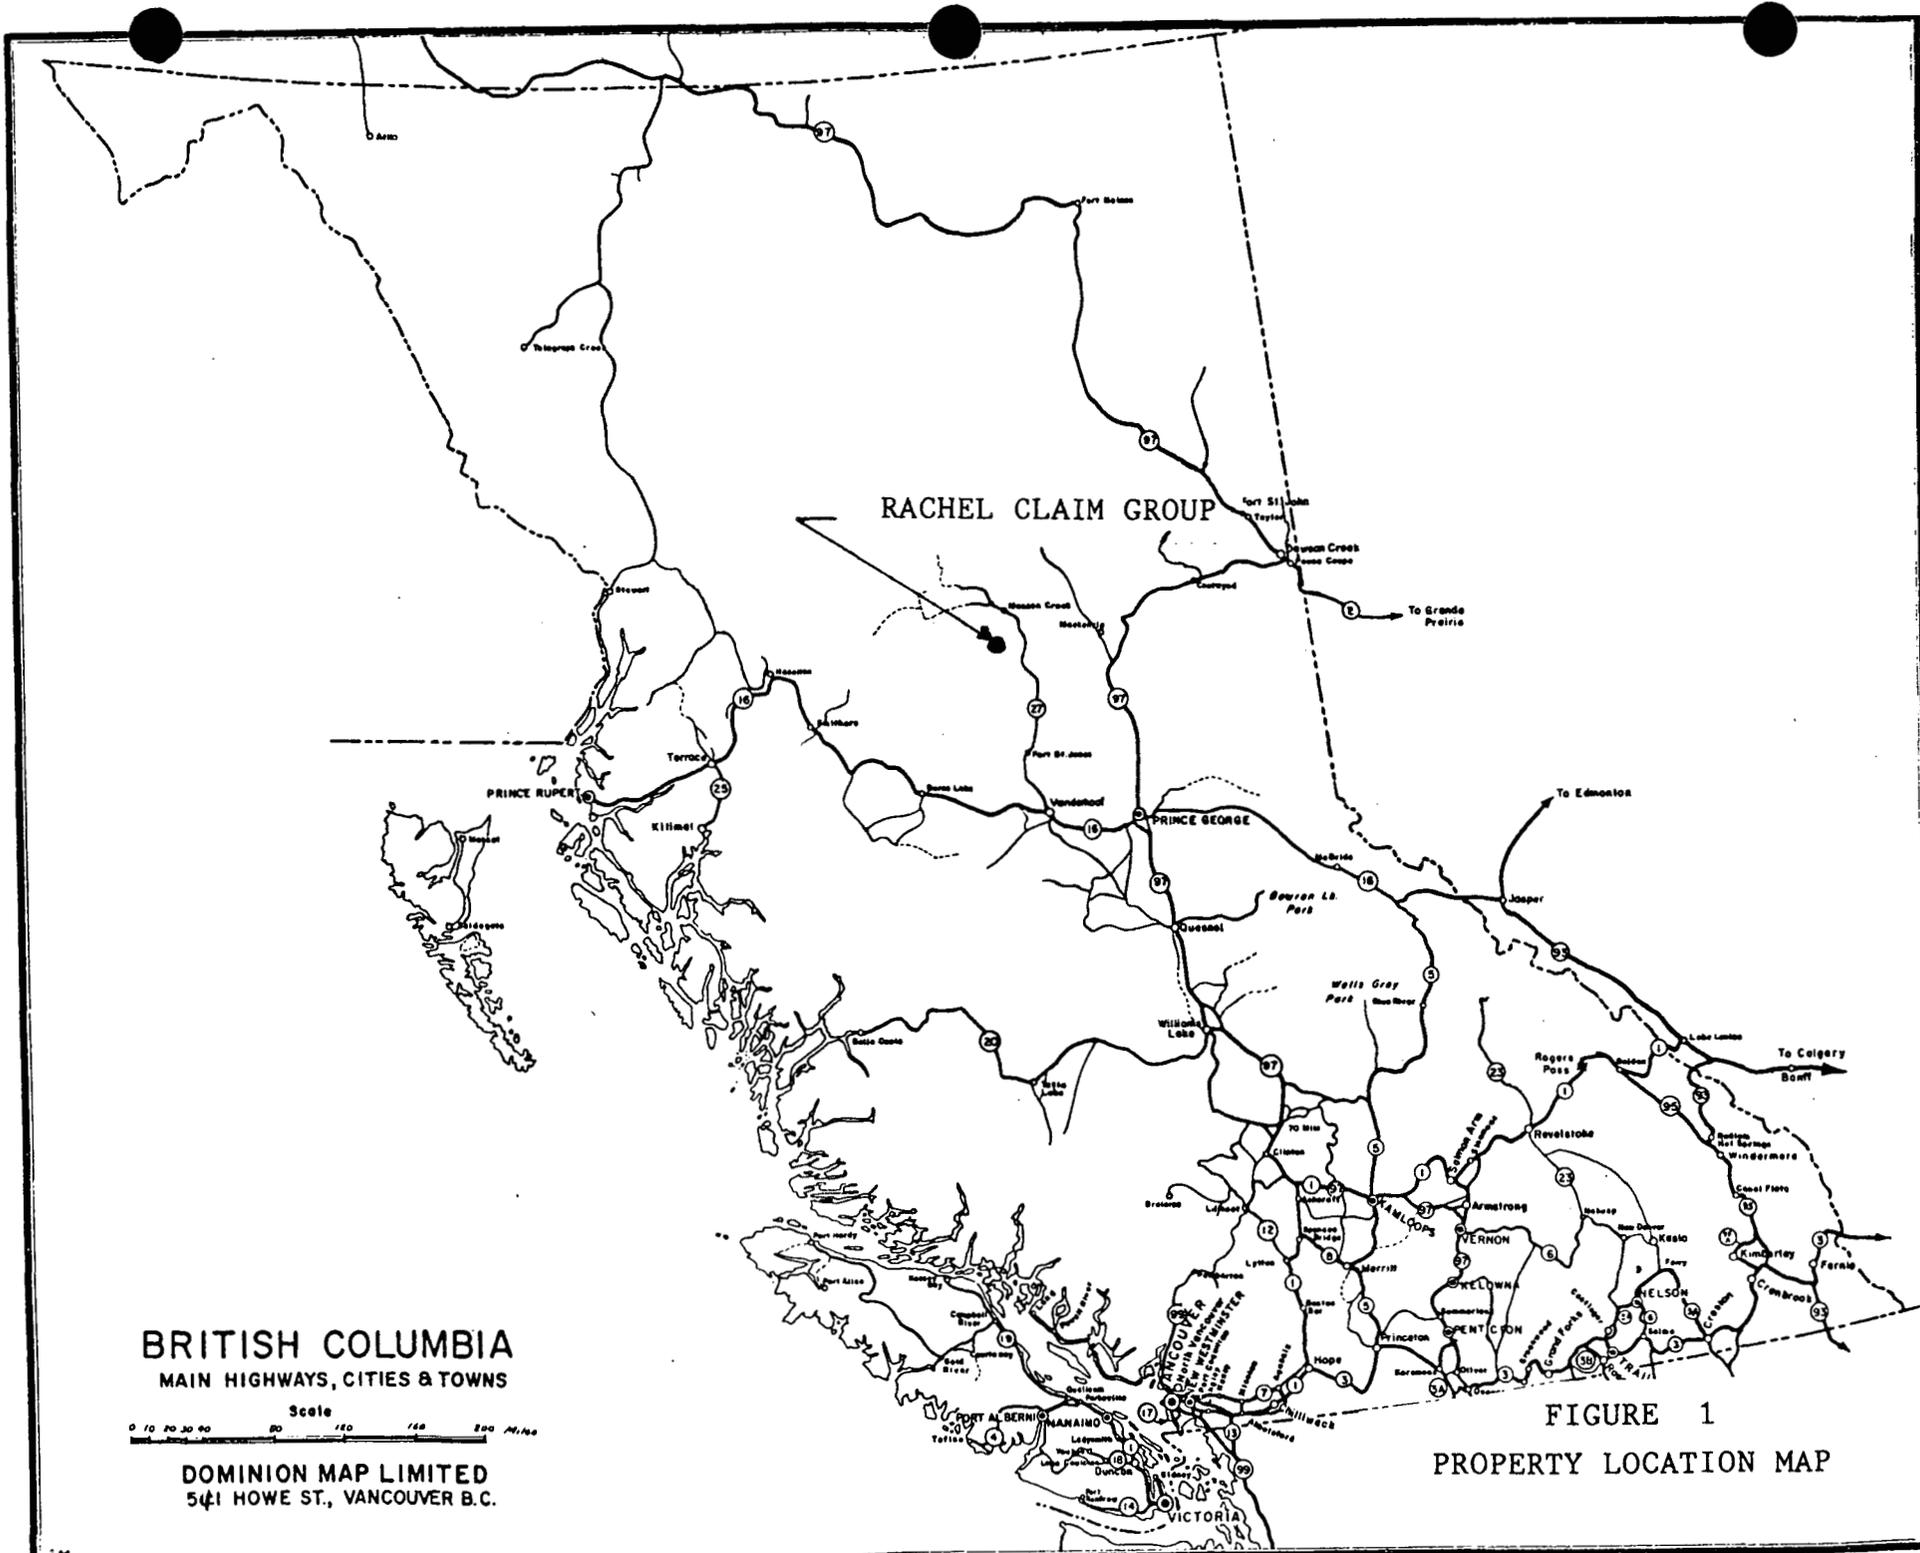

CONCLUSIONS

The geochemical and geophysical surveys carried out on the GOLD claim group during July of 1985 indicate two areas of interest which warrant further investigation. The first of these is the exposed mineralization in the Klawli showing itself. The grade of precious metal values obtained from samples in and around these workings warrants further exposure and delineation of the mineralized zone. The VLF anomalies to the south of the original showing which appear to parallel the exposed trend of mineralization should also be investigated more closely.
