SUMMARY

Two potentially economic types of gold mineralization have been identified on or adjacent to the San Juan property of Tri-West Resources Ltd.

The most significant showings comprise quartz - stibnite veins developed within a northeast trending zone of carbonized volcanics (up to 30 m wide). Recent sampling of the veins and altered wallrock has returned values of 0.125 oz/t Au and 0.015 oz/t Au respectively. Underground sampling by Stevenson (1944) yielded up to 0.60 oz/t Au. These old workings however, are no longer accessible.

Similar east - west trending mineralized zones to the east of the property have returned assays of 0.804 oz/t Au and 0.442 oz/t Au. Geochemistry and geophysics indicate that these zones may extend westward on to the Linda claim group of Tri-West Resources Ltd.

Silicified and pyritized volcanics and volcanoclastics crop out to the north of the quartz - stibnite veins, on the Cougar and Debbie claim groups. A strong copper and a weak gold geochemical anomaly indicate potential for a large tonnage, low grade gold - copper deposit.

A three phase exploration program is recommended. Detailed geologic, geochemical and geophysical surveys should be conducted in areas of known mineralization. This should be followed by cat trenching, in order to expose overburden covered mineralized zones and thus better define targets for follow up diamond drilling in the third phase of exploration.

Estimated costs of the first two programs are:

Phase 1 - \$ 23,650.00

Phase 2 - \$ 36,300.00

## INTRODUCTION

At the request of Mr. James H. Hirst (president) of Tri-West Resources Ltd., Ram Exploration Ltd. carried out the preliminary exploration program on the San Juan property. Two geologists and two assistants completed detailed geologic mapping and geochemical and geophysical surveys between October 8 and October 30, 1984. At the time of this examination, Tri-West did not hold title to the Wolf and Cougar claim groups. However, the surveys did extend onto these claim units in order to evaluate the potential of along strike mineralization from that exposed on the Debbie and Linda claims.

The following report is based on results of these surveys and a review of previous operators technical data.

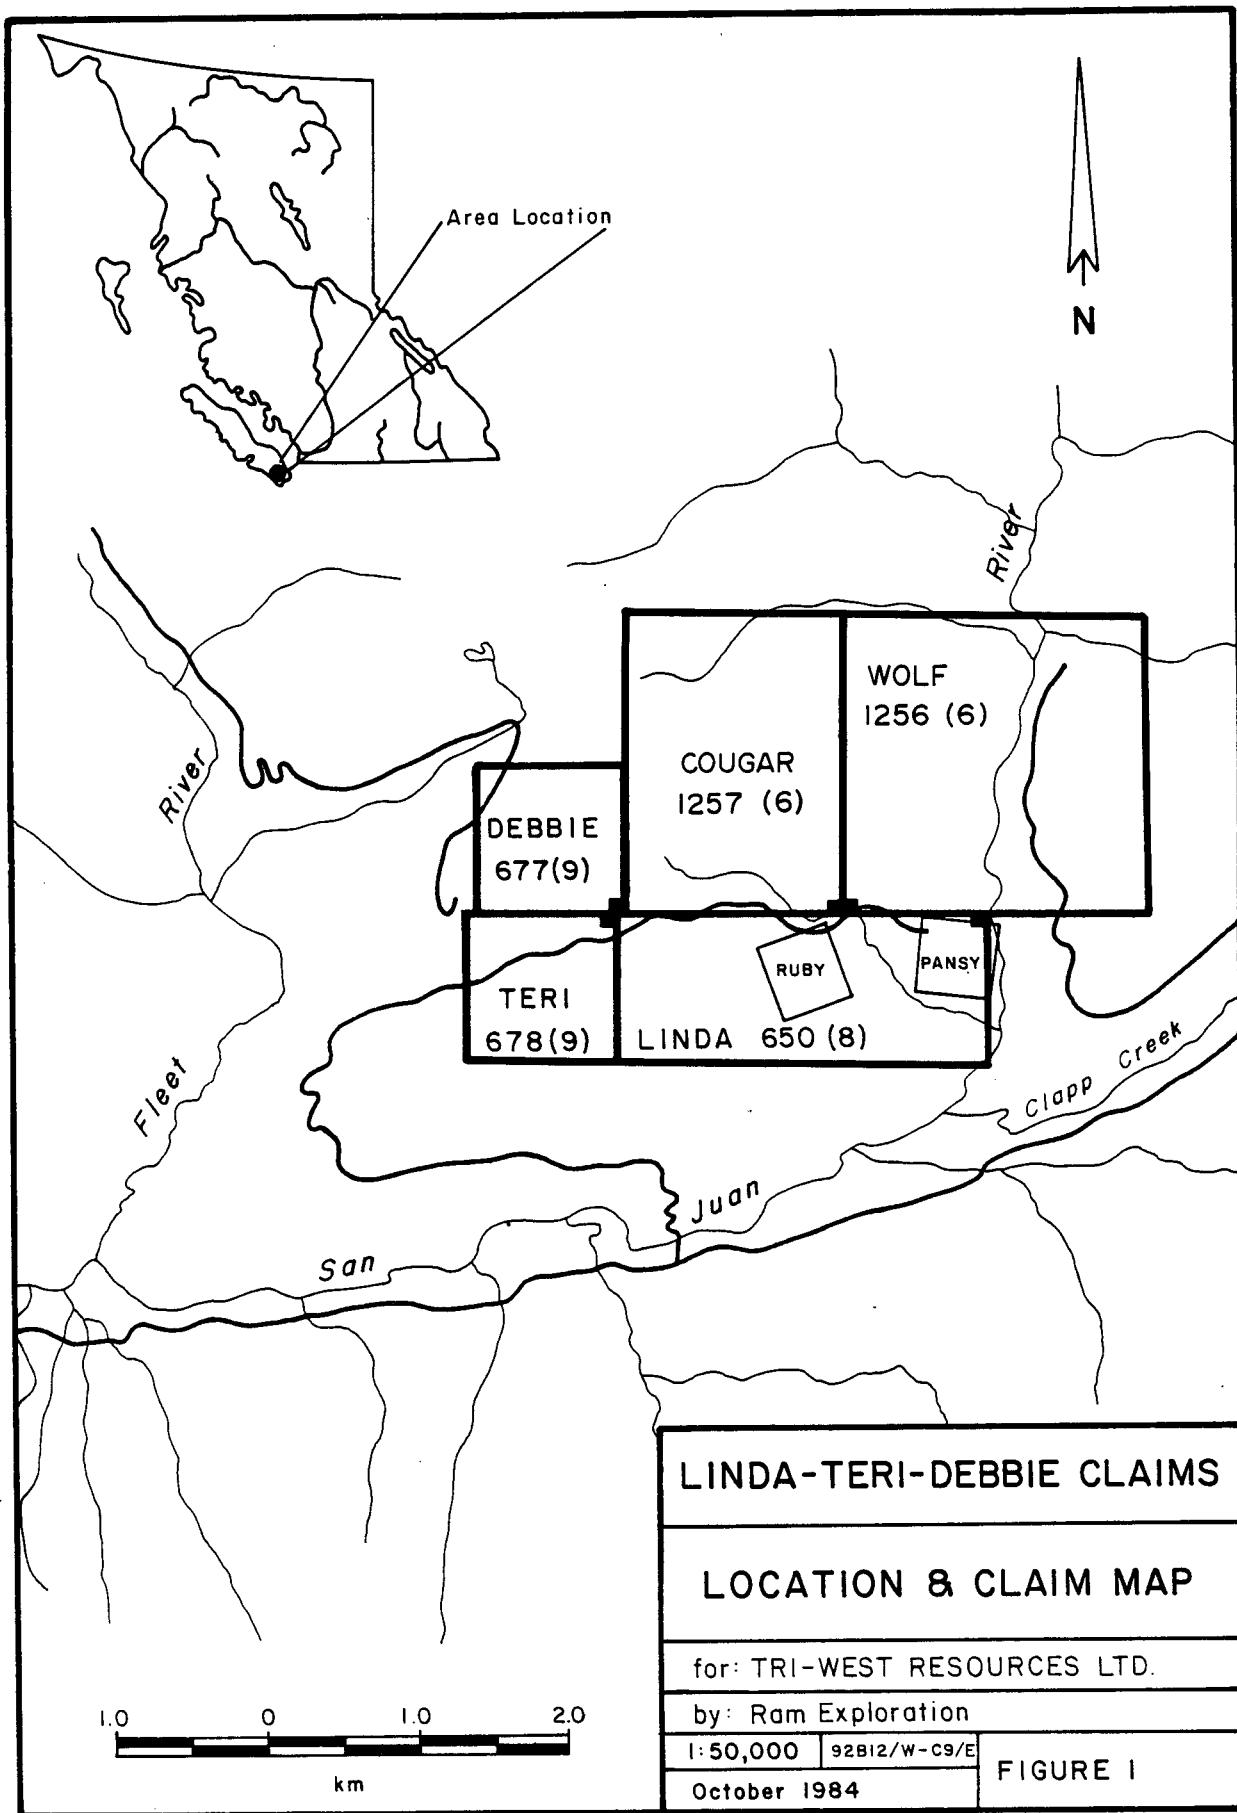

### **Location, Access and Physiography**

The San Juan property is situated in the Victoria Mining Division approximately 60 km northwest of Victoria and 30 km east of Port Renfrew, British Columbia, near the headwaters of the San Juan River; latitude 48° 37'N, longitude 124° 00'W.

Logging roads in the vicinity are numerous. Two major roads, the Port Renfrew main and the Clapp Creek spur road, pass by within 1 km of the property but both are on the opposite side of the San Juan River from the claims (Figure 1).

The northwestern portion of the Debbie claim block can be accessed by logging roads up the Fleet River from Mesachie Lake. The last kilometer of this road however, is suitable for foot traffic only. Another road did access the property from the San Juan River to the south, but it is extensively overgrown and the bridge across the San Juan River has been washed out.

Open forested, gently sloping hills dominate the Debbie, Wolf and Cougar claim groups and the northern part of the Teri and Linda claims. The central and southern portions of the Teri and Linda claims are occupied by the San Juan Fault zone. Cliffs abound and the slopes are heavily vegetated with trees and salal.

### Property

The property consists of the Linda, Teri and Debbie claim blocks, comprising a total of 18 units, recorded in the Victoria Mining Division on map sheets 92B12/W and 92C9/E. Recent acquisitions in January, 1985 have included the Wolf (16 units) and Cougar (12 units) claim blocks, located to the north of the Linda claims.

<u>Claim Name</u>	<u>No. of Units</u>	<u>Record No.</u>	<u>Registered Owner</u>	<u>Expiry</u>
Linda	10	650 (8)	Tri-West Resources	August 18/85
Teri	4	677 (9)	Tri-West Resources	September 27/85
Debbie	4	678 (9)	Tri-West Resources	September 27/85
Wolf	16	1256 (6)	Tri-West Resources	June 12/85
Cougar	12	1257 (6)	Tri-West Resources	June 12/85

### PREVIOUS WORK

The San Juan River and more generally the area underlain by the Leech River Formation on southwestern Vancouver Island, has long been known for its placer gold production. The discovery of epithermal gold veins with values up to 34 oz/t Au by Beau Pre Explorations Ltd., has given the area renewed potential for the discovery of lode gold deposits. Larger tonnage, lower grade, stratabound gold - iron - copper deposits have also been reported on Pan Island Resource Corp. and Reako Explorations Ltd. properties located to the west of the Linda, Debbie, Teri, Wolf and Cougar claim groups (Okeefe, 1984).

Showings of interest, which occur at the boundary between the Ruby claim and Tri-West's Linda, Cougar and Wolf claims, were discovered prior to World War I and were referred to as the Victory, Todd's Crevice, West Bank, West Showing and San Juan prospects (Min-file #92B-095, MMAR - 1952, A215-216).

These showings consist of northeast striking, steep southeast dipping quartz - stibnite +/- scheelite veins and lenses developed within a carbonate alteration zone (Stevenson, 1944, MMAR - 1952). A 12 m shaft was sunk during World War I and 300 m of diamond drilling was completed in 1943. Values of 0.60 oz/t with 5.4% Sb were obtained in the shaft.

Some of the quartz veins exposed on the surface were not encountered in the drilling, but the carbonate zone, which obtained widths up to 30 m traceable for 330 m along strike, did extend to depth (Stevenson, 1944). Chip samples taken across the northeast trending quartz vein averaged 0.165 oz/t Au and 6.78% Sb over a width of 1.2 m (Donaldson, 1968). Recent sampling of vein material returned 0.102 oz/t Au (Sheppard, 1983).

A geochemical survey conducted for Concorde Explorations Ltd. (Philip, 1968) confirmed the orientation of the veins and suggested that arsenic could be used to trace the gold - antimony system. A large copper anomaly, associated with strongly altered and pyritized volcanics, was also outlined on the Cougar claim group to the northwest of the quartz - stibnite - gold veins.

Similar mineralization exists on the Pansy claims to the east of the Linda claim group (Min-file #92B-061, MMAR - 1952). Here quartz and carbonate veinlets, with variable amounts of stibnite and scheelite, are hosted by limestone and marble interbedded with Bonanza Group greenstones. Several open cuts and an adit have been driven in along these structures. These showings can be traced for 125 m along strike and occur over a vertical extent of 60 m (Donaldson, 1968, MMAR - 1952). Channel samples taken along the 125 m strike length averaged 0.24 oz/t Au with 1.69% Sb over 0.5 m (Donaldson, 1968). More recent grab samples from these veins yielded 0.804 oz/t Au, 0.442 oz/t Au and 0.03 oz/t Au (Sheppard, 1983).

#### REGIONAL GEOLOGY

Southwestern Vancouver Island consists of a complex mosaic of fault blocks ranging in age from Paleozoic Sicker Group sediments and volcanics to Eocene and Oligocene clastic sediments (Muller, 1981 & 1982). The area in the vicinity of the San Juan property is predominantly underlain by Jurassic Island Intrusives, Jurassic Bonanza Group volcanics and consanguineous Westcoast Complex intrusives, Triassic to Cretaceous Leech River Formation volcanics and associated sediments and Cretaceous to Tertiary sediments, gabbroic intrusives and basaltic lavas.

Two major east - west fault systems transect the region. The northerly San Juan Fault system is interpreted to be a steep, south dipping fault zone which juxtaposes the Leech River Formation against Bonanza Group and Westcoast Complex rocks to the north. The Leech River Fault zone is parallel to and 10 km south of the San Juan Fault. It places Cretaceous to Tertiary units against the more northerly Leech River Formation.

#### PROPERTY GEOLOGY

Rock units of the Bonanza Group and Leech River Formation underlie a major portion of the San Juan property. Granitic to intermediate intrusives of the Westcoast Complex are exposed in the northwest portion of the Debbie claim group.

The San Juan Fault (Figures 2 & 3) transects the Bonanza Group in the southern portion of the Linda and Teri claims. To the east of the Linda claim, this fault places the Leech River Formation in contact with the Bonanza Group.

Several distinct rock units have been recognized within the Bonanza Group. Andesitic to basaltic volcanics (Jv - Figure 2) comprise the dominant rock type. These are brown to tan weathering and are generally fine grained and structureless, although local porphyritic and amygdaloidal phases have been noted. Chlorite is ubiquitous, a product of lower greenschist regional metamorphism.

As the San Juan Fault zone is approached, the volcanics become increasingly foliated and sheared (Jvs) and a second generation growth of chlorite can be documented. Gneissic textures, defined by alternate feldspar and chlorite rich bands, are locally developed in rocks within the fault zone. Quartz sheeting may also lend a gneissic appearance to the outcrops.

Large bodies of serpentinite (Js), up to 100 m across (exposed on L12+50E - Figure 2), compose the eastern core of the San Juan Fault zone. A second smaller body outcrops on the Teri claims (L2+50W). These units are characterized by intensely foliated, dark green chlorite rich rocks with

lighter green serpentine.

Foliations within the sheared and altered volcanics and serpentinites are generally steep north to moderate south dipping ( $60^\circ$ ). As reflected by its outcrop pattern on a topographic map (fig.3), the fault is interpreted to be steep to moderate south dipping.

A major east - west trending volcanoclastic unit ( $J_5$ ) occurs within the Bonanza volcanics and is exposed in the region of the base line on the Linda, Teri, Debbie, Wolf and Cougar claims. It is characterized by its tan to white weathering and the existence of white altered feldspar (?) and light green siliceous angular fragments up to 5cm in size. Fragments of chert and black siltstone are present locally. The matrix is composed of a fine grained siliceous material.

A series of grey green cherts, poorly bedded siliceous sandstones and siltstones, well bedded dark grey siltstones and argillites and black shales ( $J_6$ ) are exposed along the southern contact of the volcanoclastic unit, (L1+00W to 2+00E). Rare sedimentary structures, interpreted to be original bedding, indicate the units have a gross east - west, moderate ( $60^\circ$ ) north dipping orientation.

Chlorite rich tuffaceous rocks ( $J_7$ ), probably andesitic in composition, crop out along the western margin of the Debbie claims. These can be very well bedded on the centimeter scale and grading and scour textures confirm tops are to the north and east. Small (1 cm) resistant nodules probably represent rock fragments or lapilli.

Minor amounts of limestone ( $J_8$ ) have been recorded within the Bonanza Group. This fetid, black limestone crops out in the eastern portion of the Linda claims.

The Leech River Formation ( $K_s$ ) is exposed in the southeastern extremities of the Linda claim group, well south of the San Juan Fault Zone. Its contact with the Bonanza Group volcanics was not observed. It is represented by a black fissile, southeast trending shale. Compositional layering is

indistinct, but where noted it parallels the fissility.

The Upper Paleozoic to Jurassic Westcoast Complex (Pi) crops out along the western border of the Debbie claims. Small bodies of granitic to intermediate composition host inclusions of the Bonanza Group volcanics. These small bodies are probably apophyses of a larger intrusion exposed to the northwest of the property.

#### MINERALIZATION AND ROCK GEOCHEMISTRY

As discussed previously, the most important areas with respect to gold mineralization include the Ruby - Linda - Cougar claim boundary, the area to the southwest and northeast of this vein system and the region west of the Pansy claim showings.

Cat trenching by Concorde Explorations Ltd. in 1968 destroyed all surface exposures of the vein at the Ruby - Linda boundary. As a consequence, only sub - outcrop samples and float material, presumably from the shaft, were examined. This material consisted of massive white quartz with up to 10% bladed stibnite. Grab samples returned 0.125 oz/t Au (L-007 - Table 1 & Figure 2) and previous assays reported up to 0.6 oz/t Au (Stevenson, 1944). To the northeast of the shaft, near L14+00E, white quartz material with limonite coated vugs and no visible sulphide yielded 0.058 oz/t Au (L-005) while a sample of the carbonate (ankerite) alteration assayed 0.015 oz/t Au (L-006). This implies that the extensive alteration zone has potential to host significant gold values as well as containing higher grade quartz - antimony - gold veins and lenses.

No quartz - antimony veins were encountered to the west of the Pansy claim, possibly due to extensive vegetation cover. Weak gold and arsenic soil geochemical anomalies (see section 7 and Figures 4 & 6) however, indicate the potential exists for the discovery of new veins.

An extensive zone of silica - pyrite alteration is developed within the andesitic (Jv) and volcanoclastic (Jb) units to the northwest of the shaft.

The main alteration zone is over 100m in width and extends for 600 m+ to the east and west (Figures 2 to 5). A second zone (which may be the northern extension of the main zone) is developed along the river bed to the north. If these two zones are continuous, it implies a vertical extent of over 150 m. Other silicified - pyrite rich areas occur to the west and northwest on the Debbie claim group.

Within these zones pyrite appears mainly as disseminations, but also occurs in the form of veinlets and fracture coatings. Pyrite can make up to 5% of the rock with local concentrations in excess of 25%. Chlorite +/- sericite alteration is developed locally within the silicified area. Numerous rock samples were taken and geochemically analysed for Au. Several were also analysed by ICP. A strong copper and moderate arsenic association was noted. This corroborates previous soil geochemistry performed for Concorde Explorations Ltd. (Philip, 1968). Some samples were also weakly anomalous with respect to gold (up to 65 ppb) indicating this zone may have potential to host a large tonnage, low grade, gold - copper deposit.

The silica - pyrite zone appears to be a separate mineralizing event from that which formed the quartz - stibnite - gold veins. Both are spatially separated by fresh volcanics. The silicified - pyritized volcanics and volcanoclastics have an associated enrichment in Cu and contain only background levels of Sb, whereas the quartz - stibnite veins have no copper signature and are associated with extensive carbonate (ankerite) alteration. Selected samples from both zones were analysed for mercury. The silicified volcanics contained only trace levels of mercury while minor amounts (up to 50 ppb) were detected in the quartz - stibnite veins.

The quartz - stibnite veins are thought to be epithermal in origin. The silicified zones may be representative of a fault controlled hydrothermal event, but their association with the volcanoclastic unit, combined with their copper geochemical signature, may imply a volcanogenic exhalative origin. Both models yield potential for a large tonnage, low grade copper - gold deposit.

## GEOPHYSICS

A VLF-EM 16 survey was conducted along pre-established, north-south, 150 m spaced grid lines. Five lines were also established on the Cougar claims, in order to evaluate the silicified - pyrite alteration zone. Recordings were taken at 25 m intervals and a frequency of 17.8 KHz (Cutler, Maine - NAA) was used to test east-west trending conductors. The receiving instrument was a Geonics VLF-EM 16. The data was collected and reduced by Fraser Filtering, the results of which are shown on figure 3.

The most prominent conductor is the San Juan Fault zone, but this structure does not appear to be significant with respect to mineralization (see Figures 3 to 6). Other less prominent but significant anomalies are coincident with silicified volcanic and volcanoclastic zones exposed on the Cougar and Debbie claims. These are also associated with weak gold and copper soil anomalies (Figures 3 and 4).

A continuous southeast trending (?) conductor occupies the southern portion of the Debbie claims. Although outcrops in this region are few, the anomaly is not believed to be representative of a zone of alteration. It may be in part however, coincident with the east-west trending volcanoclastic unit (Figure 2).

Isolated conductive zones in the northeastern portion of the Linda claims are as yet unexplained. They do not appear to be coincident with known quartz - stibnite veins or with soils anomalous in gold or arsenic.

The VLF-EM 16 appears to be successful in distinguishing zones of intense alteration and in outlining the volcanoclastic unit. It has not however, been successful in delineating the quartz - stibnite veins and their associated structures.

## SOIL GEOCHEMISTRY

Soil samples were taken along the pre-established grid, at 25 m intervals. No

samples were taken in areas of poor soil. Analyses were performed at Vangeochem Lab Ltd. in Vancouver.

Overburden is shallow in the northern part of the property (1m) and outcropings are abundant. Soils are poorly developed and are generally representative of the "C" horizon. The southern portion of the grid (from 2+00S on most lines) changes from steep cliff faces and associated talus slopes to a more gentle, heavily vegetated slope. This southern area has better developed soils from which the "B" horizon could be sampled. All "B" and "C" horizon samples were collected from a depth of 20 to 40 cm.

All samples were initially geochemically analysed for trace amounts of gold. From the ICP results of the rock samples, it was determined that the northern silicified zones were anomalous in Cu and As while the quartz - stibnite veins were anomalous in Sb, weakly anomalous in As and contained only background levels of Cu. Consequently, the northern lines were analysed for Cu and As while the southern lines for As and Sb. Several north and south lines were also tested for Sb and Cu responses respectively.

After a brief examination of the data, it was decided to treat all the soil samples as a single population for geostatistical purposes. Histograms and probability plots (Sinclair, 1981) indicate that the threshold value for anomalous Au in soils was 25 ppb, anomalous Cu was 100 ppm and anomalous As was 10 ppm. All Sb values reflected background concentrations.

#### Gold

All non isolated Au values greater than 20 ppb were contoured and are illustrated on Figure 4.

A strong Au anomaly (up to 105 ppb) corresponds with the quartz - stibnite vein at the Ruby - Linda claims boundary. Another anomalous zone (up to 35 ppb) may be representative of the westward continuation of the Pansy claim showings.

Soils containing up to 65 ppb Au are associated with the silica - pyrite alteration zones on the Cougar and Debbie claims.

### Copper

Soils anomalous in copper appear to be restricted to the northern part of the grid, (Figure 5). The strongest anomaly (L5+00E) has a restricted east-west extent, but is coincident with an area of silica - pyrite alteration. Weaker anomalous zones occur to the east and are also associated with the altered volcanics and volcanoclastics. These zones parallel and occur upslope from an associated (?) gold anomaly.

A major copper anomaly was detected in the southeast corner of the Debbie claims. Limited exposure suggests that this anomaly is not associated with a zone of alteration.

### Arsenic

Arsenic corresponds well with gold anomalies on the southern portion of the grid (Figures 4 and 6). In particular it highlights the quartz - stibnite veins at the Linda - Ruby boundary.

Weaker anomalous zones occur to the north and northwest, but their relationship to the silicified zones and the copper and gold anomalies is more ambiguous.

### Antimony

Antimony in soils was initially determined by A.A.S., but only background levels were detected. Soils collected in the vicinity of the quartz - stibnite - gold vein system were re-analysed by ICP, yielding significantly greater antimony values (Appendix 4). Consequently, soils were rerun by the ICP method. The bulk of these however, still reflected only background levels.

### CONCLUSIONS AND RECOMMENDATIONS

Tri-West's San Juan property and the surrounding claims host two distinct

types of mineralization.

Of primary importance are a series of northeast - southwest trending quartz - stibnite veins and their associated ankeritic alteration zone. Both the veins and the altered host rocks yield significant gold (0.125 oz/t Au and 0.015 oz/t Au respectively) and antimony values.

Similar mineralization, running up to 0.804 oz/t Au, occurs on the Pansy claims to the east. Weak gold and arsenic soil anomalies suggest this mineralization may extend westward onto the Linda claim group.

An extensive area of silica - pyrite +/- chlorite - sericite alteration is associated with andesitic and volcanoclastic rocks on the Cougar and Debbie claim groups. Weak gold and copper soil anomalies and an associated VLF conductor occur within this zone. Low but weak anomalous gold values were obtained in rocks collected from this area.

It is recommended that a three phase exploration program be undertaken.

More detailed geological, geochemical and geophysical surveys should be conducted in order to better define areas of known mineralization and their possible extensions. Geophysical surveys should include a closer spaced VLF/EM program, to test the pyrite - silica alteration zones. A magnetometer survey may be important in delineating quartz - antimony - gold bearing systems. This phase of exploration should also include limited hand trenching in the vicinity of the shaft and reconnaissance programs on the Wolf and Cougar claims.

The second exploration program should consist of road rehabilitation and cat trenching of known showings, to better define targets for drilling in the third exploration phase.

Estimated costs of phase 1 and 2 are \$ 59,950.00 (table 2).

Respectfully submitted:

Gregory S. Ecowe, M.Sc., P.Geol.

SUBJECT: Analytical procedure used to determine Aqua Regia soluble gold in geochemical samples

1. Method\_of\_Sample\_Preparation

- (a) Geochemical soil, silt or rock samples were received in the laboratory in wet-strength 4" x 6" Kraft paper bags or rock samples sometimes in 8" x 12" plastic bags.
- (b) The dried soil and silt samples were sifted by hand using a 8" diameter 80-mesh stainless steel sieve. The plus 80-mesh fraction was rejected and the minus 80-mesh fraction was transferred into a new bag for analysis later.
- (c) The dried rock samples were crushed by using a jaw crusher and pulverized to 100-mesh or finer by using a disc mill. The pulverized samples were then put in a new bag for later analysis.

2. Method\_of\_Digestion

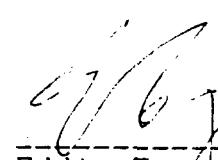

- (a) 5.00 - 10.00 grams of the minus 80-mesh samples were used. Samples were weighed out by using an electronic micro-balance into beakers.
- (b) 20 ml of Aqua Regia (3:1 HCl : HNO<sub>3</sub>) were used to digest the samples over a hot plate vigorously.
- (c) The digested samples were filtered and the washed pulps were discarded and the filtrate was reduced to about 5 ml.

- (d) The Au complex ions were extracted into diisobutyl ketone and thiourea medium. (Anion exchange liquids "Aliquot 336").
- (e) Separate Funnels were used to separate the organic layer.

3. Method\_of\_Detection

The gold analyses were detected by using a Techtron model AA5 Atomic Absorption Spectrophotometer with a gold hollow cathode lamp. The results were read out on a strip chart recorder. A hydrogen lamp was used to correct any background interferences. The gold values in parts per billion were calculated by comparing them with a set of gold standards.

- 4. The analyses were supervised or determined by Mr. Conway Chun or Mr. Eddie Tang and his laboratory staff.

SUBJECT: Analytical procedure used to determine hot acid soluble for Mo,Cu,Pb,Zn,Ag in geochemical silt and soil samples.

1. Method\_of\_Sample\_Preparation

- (a) Geochemical soil, silt or rock samples were received in the laboratory in wet-strength 4" x 6" Kraft paper bags or rock samples sometimes in 8" x 12" plastic bags.
- (b) The dried soil and silt samples were sifted by hand using a 8" diameter 80-mesh stainless steel sieve. The plus 80-mesh fraction was rejected and the minus 80-mesh fraction was transferred into a new bag for analysis later.
- (c) The dried rock samples were crushed by using a jaw crusher and pulverized to 100-mesh or finer by using a disc mill. The pulverized samples were then put in a new bag for later analysis.

2. Method\_of\_Digestion

- (a) 0.50 gram of the minus 80-mesh samples was used. Samples were weighed out by using a electronic micro-balance.
- (b) Samples were heated in a sand bath with nitric and perchloric acids (15% to 85% by volume of the concentrated acids respectively).
- (c) Minimum of 5000 ppm of AlCO<sub>3</sub> was added to each samples when Mo analysis is required, digested samples were diluted with demineralized water to a fixed volume and shaken

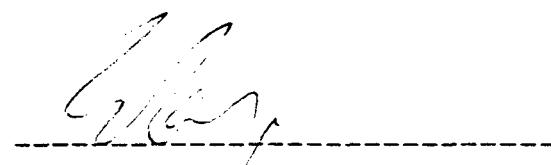

3. Method\_of\_Analysis

Mo,Cu,Pb,Zn,Ag analyses were determined by using a Techtron Atomic Absorption Spectrophotometer Model AA5 with their respective hollow cathode lamps. The digested samples were aspirated directly into an air and acetylene mixture flame. The results, in parts per million, were calculated by comparing a set of standards to calibrate the atomic absorption units.

4. Background\_Correction

A hydrogen continuum lamp is used to correct the Silver background interferences.

5. The analyses were supervised or determined by Mr. Conway Chun or Mr. Eddie Tang and the laboratory staff.

SUBJECT: Analytical procedure used to determine multiple elements  
in hot acid soluble by Induction Couple Plasma  
Spectrometer (ICP) analysis.

1. Method\_of\_Sample\_Preparation

- (a) Geochemical soil, silt or rock samples were received in the laboratory in wet-strength 4" x 6" Kraft paper bags or rock samples sometimes in 8" x 12" plastic bags.
- (b) The dried soil and silt samples were sifted by hand using a 8" diameter 80-mesh stainless steel sieve. The plus 80-mesh fraction was rejected and the minus 80-mesh fraction was transferred into a new bag for analysis later.
- (c) The dried rock samples were crushed by using a jaw crusher and pulverized to 100-mesh or finer by using a disc mill. The pulverized samples were then put in a new bag for later analysis.

2. Method\_of\_Digestion

- (a) 0.500 gram of -80 mesh sample was used.
- (b) Samples were digested in a hot water bath with diluted aqua regia acids.
- (c) The digested samples were diluted to a fixed volume and shaken well.

**3. Method\_of\_Analysis**

The analyses were determined by using a Jarrel Ash ICAP model 9000 direct reading emission spectrometer with an inductively coupled plasma excitation source. Background and inter-element corrections (IEC'S) were applied. All data is compiled into an Apple IIe computer, stored on floppy disk and printed by an Epson 100 dot-matrix printer.

- 4.** The analyses were supervised by Mr. Wade Reeves and Mr. Conway Chun of Vangeochem Lab Ltd. and their staff.

SUBJECT: Analytical procedure used to determine Antimony in geological samples.

1. Method of Sample Preparation

- (a) Geochemical soil, silt or rock samples were received in the laboratory in wet-strength 4" x 6" Kraft paper bags or rock samples sometimes in 8" x 12" plastic bags.
- (b) The dried soil and silt samples were sifted by hand using a 8" diameter 80-mesh stainless steel sieve. The plus 80-mesh fraction was rejected and the minus 80-mesh fraction was transferred into a new bag for analysis later.
- (c) The dried rock samples were crushed by using a jaw crusher and pulverized to 100-mesh or finer by using a disc mill. The pulverized samples were then put in a new bag for later analysis.

2. Method of Digestion

- (a) 0.50 gram samples of the minus 80-mesh fraction were weighed out by using a electronic micro-balance into the test tubes.
- (b) Tartaric acid and nitric acid were added to the samples and allowed to sit overnight.
- (c) The samples were digested in a hot water bath for 2-3 hours.

(d) The samples were shaken and diluted with demineralized water to a fixed volume settled.

3. Method\_of\_Analysis

Sb analysis is determined by using a Techtron Atomic Absorption Spectrophotometer Model AA4 or Model AA5 with the Sb hollow cathode lamp. The digested samples were aspirated directly into an air and acetylene flame. The results in parts per million were calculated by comparing a set of standards to calibrate the atomic absorption unit and displayed in a strip chart recorder.

4. The analyses were supervised or determined by Mr. Conway Chun or Mr. Eddie Tang and the laboratory staff.

DETECTION LIMIT

1

nd = none detected

-- = not analysed

is = insufficient sample

**LEGEND**

TRIASSIC TO CRETACEOUS LEECH RIVER FORMATION	
Ks	Siltstone, Shale, Phyllite.
JURASSIC BONANZA	
Jv	Andesite - Basalt, chlorite rich.
Jt	Lepilitic Tuff - chlorite rich.
Jb/Jc	Volcanoclastic Breccia/Chert - Siliceous Siltstone.
JVs	Andesite - Basalt - Intensely Sheared/Foliated, chlorite rich.
Js	Serpentinite.
JL	Limestone.
UPPER PALEOZOIC TO JURASSIC WEST COAST COMPLEX	
Pi	Granite To Intermediate Intrusives.
Silico-Pyrite +/- Chlorite - Sericitic Alteration.	
Carbonate Alteration.	
Geological Contact - Approximate/Assumed.	
Shear.
