1. SUMMARY AND CONCLUSIONS

The Gros Property is situated about 57 kilometers northwest of Ft. St. James in central British Columbia. The property consists of two claims of 32 units (GROS 1 and 2) held by Cominco Ltd. under joint venture with Equinox Resources Ltd. and Rennex Resources Ltd. Additional ground was staked in 1986 by Equinox Resources Ltd. to the north, ABE 1 - 9 and PINCH 1 - 4, and south, CAB 1 - 6, amounting to 261 units overall.

The Gros property and surrounding claims straddle the Pinchi fault, which juxtaposes Cache Creek Group rocks to the west and Takla Group rocks to the east. A gold-bearing boulder of quartz-carbonate-mariposite rock, found on the Gros 1 claim, is presumed to have its provenance in an altered zone in the Pinchi fault.

A reverse circulation drill program was carried out in an attempt to locate the bedrock source of the mineralized boulder and/or identify a glacial geochemical dispersion pattern associated with that source. A total of 2407 feet (734 m) was drilled in 21 holes, of which 14 successfully reached and penetrated bedrock at depths ranging from 26 to 177 feet (8 - 54 m). Some 225 samples of overburden and bedrock were collected, usually over five-foot intervals (1.5 m).

Forty selected overburden and bedrock samples were analyzed geochemically for gold and arsenic. Only one overburden sample is weakly anomalous in gold (23 ppb) and arsenic (30 ppm). However, the sample is a gravel and, hence, the geochemical data may not be significant.

It is concluded that the source of the mineralized boulder on the Gros claims lies outside the area drilled, probably some unknown distance to the north, given presumed directions of ice movement during the glacial period. It is also believed that, given potential rewards, further effort is warranted to find the boulder's source. Accordingly, a follow-up program involving soil geochemistry, ground magnetics, prospecting and reverse circulation drilling (850 meters or 2790 ft.) is recommended. The cost of this program is estimated to be \$100,000.

2. INTRODUCTION

This report describes an overburden drilling program using reverse circulation on the Gros claims, Omineca Mining Division, British Columbia. The object of the drilling program was to identify the glacial dispersion train and/or the bedrock source of a gold-bearing boulder discovered by Cominco Limited in the course of the 1983 field season.

3. GENERAL PROPERTY DESCRIPTION

3.1 Location and Access

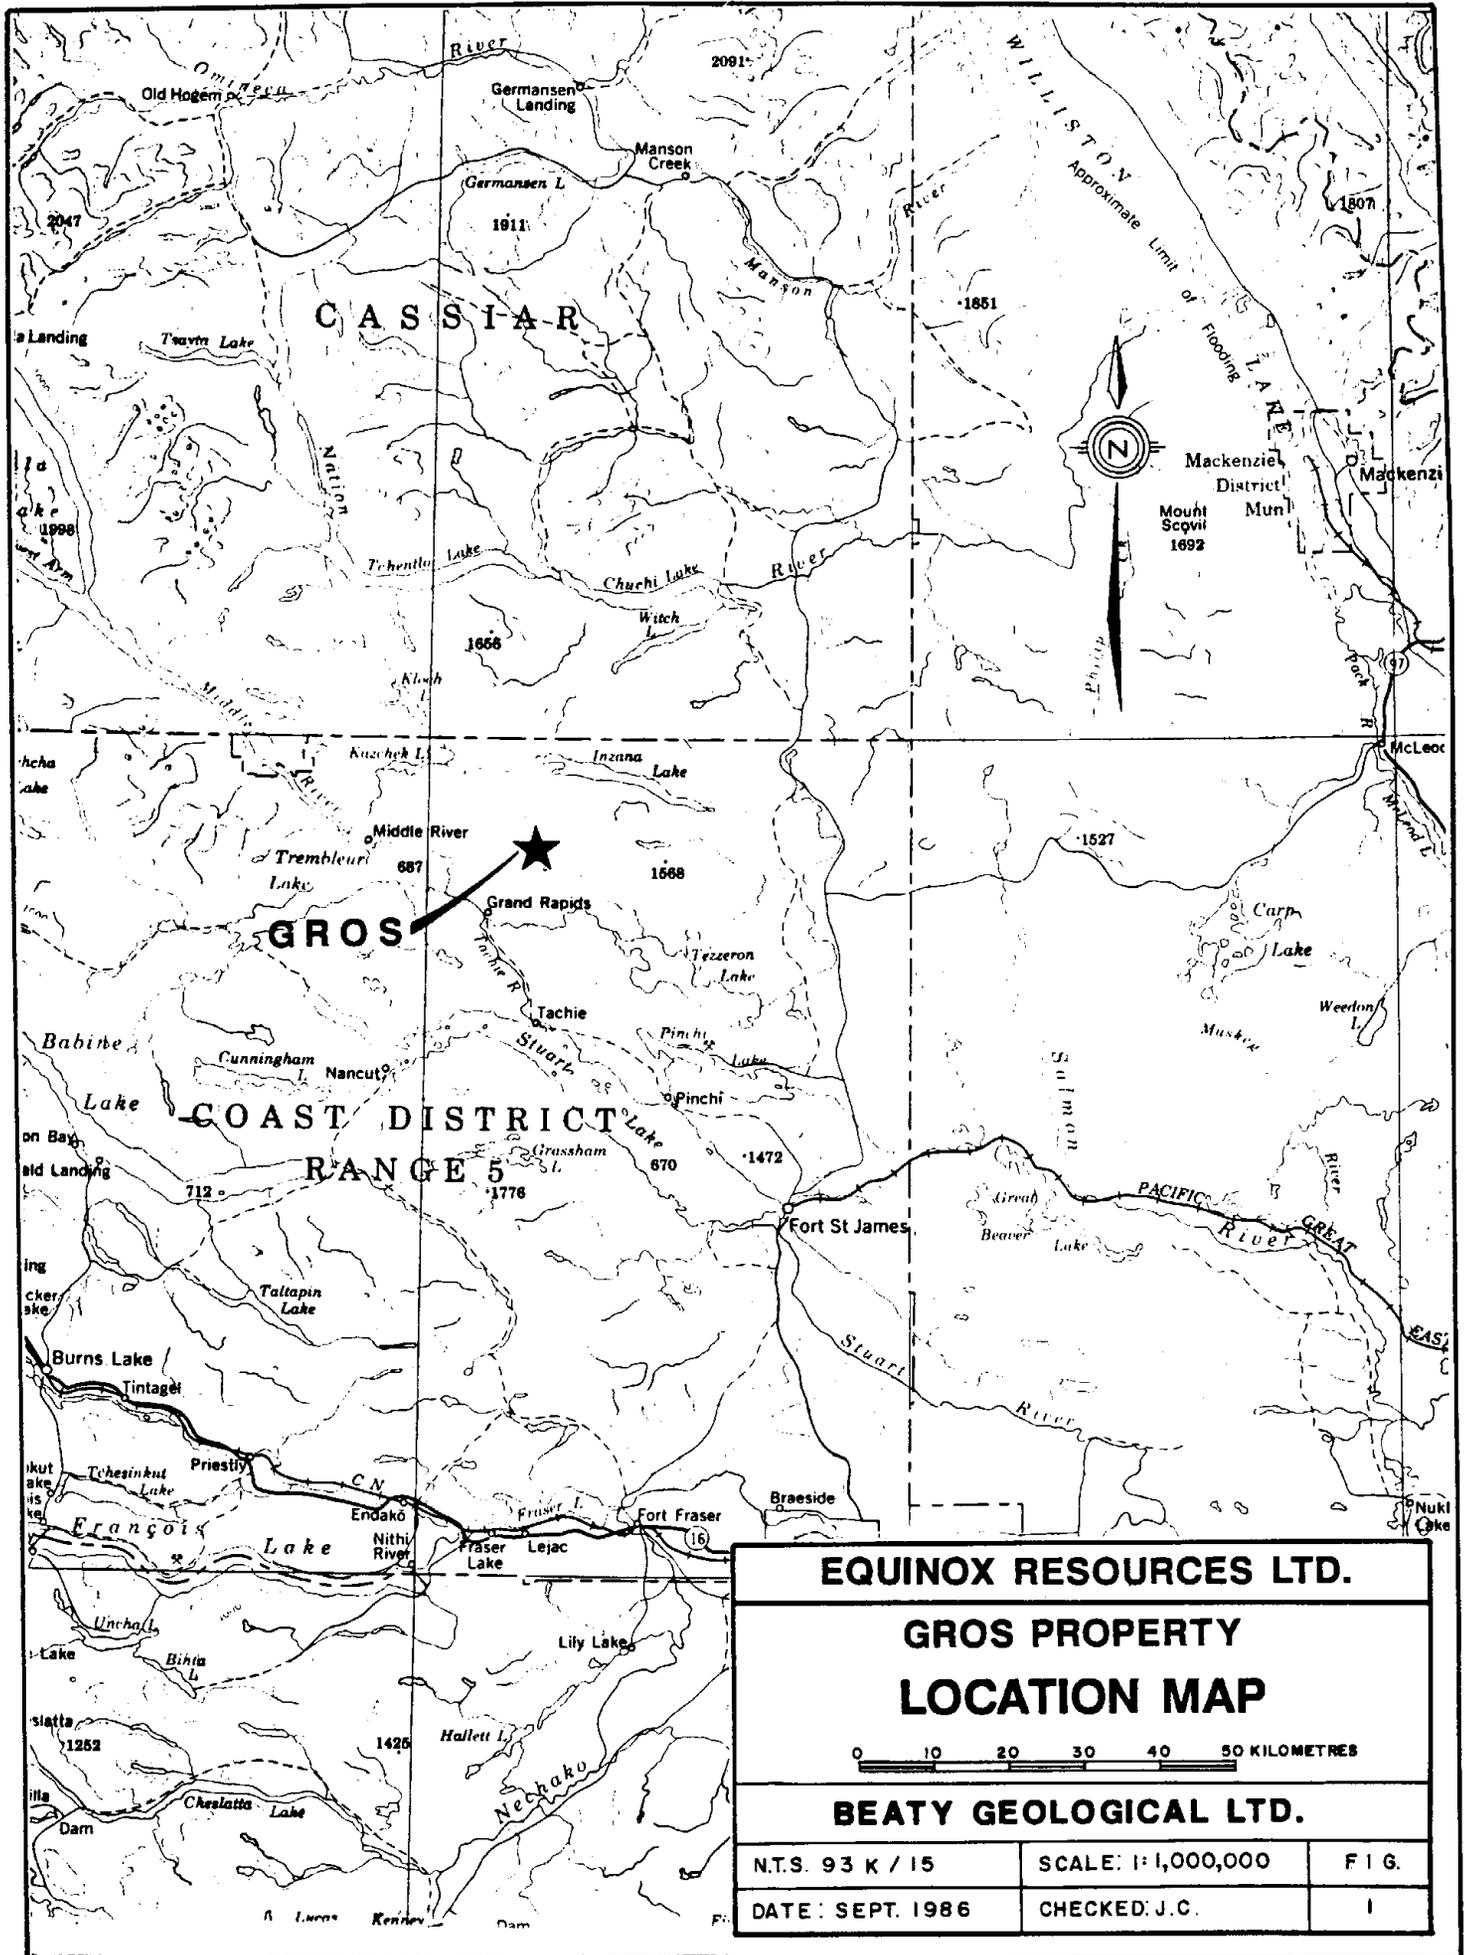

The Gros property is situated some 57 kilometers northwest of Ft. St. James and 15 kilometers east of Trembleur Lake in central British Columbia (Figure 1). The road distance between Ft. St. James and the centre of the property is about 80 km, requiring just over one hours driving. Access is via the Leo Creek road, a well-maintained gravel road used year round by logging companies in the area. The road is suitable for all types of vehicles although 4WD's, or at least 2WD pick-ups, are recommended for all weather travel.

3.2 Physical Features

The property lies within the Nechako Plateau physiographic province, which forms a part of the extensive interior plateau of the Canadian Cordillera. The mean elevation is about 800 meters (2600 ft) and topography is generally subdued, relief being rarely more than 100 m (330 ft) locally. Drainage is restricted, giving rise to swampy conditions in many parts of the property. The main stream systems are Kuzkwa River and Grostete Creek, both of which flow south easterly into Tezzeron Lake.

Forest cover is heavy and extensive, comprising mainly pine, spruce, balsam and poplar. Logging activities are important in the vicinity - Apollo Forest Products operates a logging camp at km 46 on the Leo Creek road just 20 km north of the Gros claims.

Much of the area is covered by a thick mantle of glacial drift so that outcrops are relatively rare. Within the Gros claims, these superficial deposits appear to be substantially fluvial/lacustrine in nature and were formed late in glacial times when a large lake extended from present-day Prince George to the vicinity of the property.

3.3 Claim Data

The original property comprises the Gros 1 and 2 claims, which were staked in 1983 by Cominco Ltd. During the 1986 field season, additional claims were staked by Equinox Resources Ltd. and Rennex Resources Ltd. including the ABE 1 - 9, PINCH 1 - 4 and CAB 1 - 6 (Figure 2). Pertinent details of the claims are tabulated below.

<u>Claim Name</u>		<u>Units</u>	<u>Record No.</u>	<u>Recording Date</u>

		<u>293</u>		

The claim block straddles approximately 35 kilometers of the trace of the Pinchi Fault. Of the 293 units, 261 belong to the ABE, PINCH and CAB groups.

4.0 PREVIOUS WORK

During 1983, Cominco discovered a mineralized boulder in glacial till at the 26.1 km mark on the Leo Creek road (see Figure 3 for location), within the limits of the Gros 1 claim and not far east of the Pinchi fault. The boulder consisted of quartz and ferroan magnesite with accessory disseminated chromite and distinct green mariposite, the assemblage

probably resulting from the alteration of an ultramafic rock. The boulder also contained disseminated pyrite and arsenopyrite and assayed 8.1 ppm Au (0.26 oz/ton) as an average of three separate analyses. The boulder was consumed in the analytical process.

Geochemical surveys of the claim area in 1983 failed to identify any geochemical gold dispersion pattern in the glacial till and no other gold mineralized boulders were found within the claim boundaries. However, similar quartz-carbonate-mariposite altered rocks are known to occur within the Pinchi fault zone, for example at the Pinchi-mercury mine. Accordingly, it was concluded that the Pinchi fault is the likely source of the gold-bearing boulder.

A ground magnetic survey in 1984 identified a positive magnetic feature, presumed to be due to ultramafics, along the fault just west of the boulder discovery site. It was recommended that the magnetic anomaly be tested by overburden percussion drilling to determine the presence of quartz-carbonate altered rocks within or peripheral to the presumed ultramafic rocks in the fault zone.

A more detailed description of the work done is provided in Cominco's 1983 and 1984 project reports on the Gros claims.

5.0 GEOLOGY

The Gros property is transected by the Pinchi fault, a major north northwest-south southeasterly structure, which can be traced for over 200 kilometers in the Ft. St. James area. The fault juxtaposes Permo-Carboniferous Cache Creek rocks on the west and Triassic Takla rocks on the east (Figure 3).

The Cache Creek group is dominantly a thick steeply dipping sequence of sedimentary rocks with some minor volcanics. Typically, the important lithologies are massive limestone, phyllite and ribbon chert of which the first mentioned is bent exposed as steep prominent bluffs west of the Pinchi fault zone.

The Takla group is a volcano - sedimentary sequence mainly comprising well-bedded turbidites-greywackes and siltstones - in the vicinity of the Gros claims. Some distance to the south near the Juzkwa River mafic autobreccias and pillow lavas are also exposed. Dips are steep.

Ultramafic bodies have been emplaced along the Pinchi fault. Locally these rocks are hydrothermally altered to quartz-carbonate-mariposite assemblages, which are locally mercury bearing, for example, the Pinchi deposit. As mentioned earlier, this rock type can be auriferous - such as within the boulder found on the Gros property. In general, though exploration along the Pinchi fault in the past has been hampered greatly by lack of exposure due to heavy glacial cover.

6.0 1986 PROGRAM

6.1 General

The work in 1986 consisted of an overburden/bedrock reverse circulation drill program on Gros 1 and 2. Briefly, the following was undertaken:

- (i) access roads and 28 drill sites prepared by D6 bulldozer,
- (ii) 21 reverse circulation holes drilled - GRC-1 to 21,
- (iii) 225 overburden/bedrock drill samples collected,
- (iv) 40 samples analyzed geochemically for gold and arsenic.

Drill sites/holes and access roads etc. are shown in Figure 3.

The purpose of the drill program was to identify the source of a gold-bearing boulder located at approximately the 26.1 km mark on the Leo Creek logging road (Figure 3). It was also hoped to outline a gold geochemical dispersion pattern, or which the boulder was a part, associated with the source, assuming a northwest to southeast glacial direction.

6.2 Access

Two days of bulldozer time were required to provide access and clear drill sites. A total of about two kilometers of road was driven.

6.3 Reverse Circulation Drilling

A total of 2407 feet (734 m) was drilled in 21 holes (GRC-1 - 21) from July 23 to August 3, 1986 inclusive (see Figure 3 for hole locations). The contractor, Tonto Drilling, provided a heavy (25 ton) T685 DHH Schramm truck-mounted rig

and two-men crew for the job. A support track for tools and water and rod haulage was also included. Drilling tools consisted of 10 20-foot 4-3/4" dual-tube rods with 5-1/4" carbide-tipped tricone bits. The rig is capable of both air-flush and water-flush means of sample recovery. Fifty feet of 6-1/2" casing was kept on hand in case of excessively bad ground conditions.

Drill samples were usually collected on five-foot intervals (1.5 m) and stored in heavy duty plastic bags. In the sampling procedure, cuttings from the hole passed first directly through a cyclone followed by two banks of Jones splitters to provide a 1/4 split sample of about 20 lbs (9 kg) on average. Depending on ground conditions down the hole, however, sample recoverings could and did vary considerably.

Drill logs were kept routinely during the entire program and these are presented in Appendix I. As time permitted, small samples of overburden and bedrock material were panned at the site to identify the nature of the coarse fraction and heavy minerals present. The combination of sampling, logging and panning required field staff to be in attendance at all times.

6.4 Samples

All 225 samples (2 - 3 tonnes) collected were shipped by truck to Acme Analytical Laboratories Ltd., 852 E. Hastings St., Vancouver, B.C. Of these, an initial 40 samples were selected for geochemical analyses for gold and arsenic. Acme's analytical procedures are given in Appendix II.

7.0 RESULTS

7.1 Drilling

Fourteen of the 21 holes drilled successfully penetrated bedrock. One unsuccessful hole was thought to have been very close to bedrock. Of the others, two were abandoned due to ground conditions in thick sands and gravels at depth (170 - 200 feet), one due to logistical problems (the rig and water truck became bogged down) and three due to minor equipment/driller orientation problems early in the program.

Nevertheless, the 14 successful holes are thought to provide a more-than-adequate picture of the bedrock geology and sampling density in the area of interest as shown in Figure 3. The geology is essentially as expected, that is, structurally controlled serpentinite within the Pinchi fault separating Takla greywackes to the east from Cache Creek carbonates and chert to the west. No source of the quartz-carbonate-mariposite-(Au) boulder found by the Leo Creek road was identified. Apart from minor pyrite in the Takla rocks and magnetite elsewhere, there was little or nothing of obvious economic-mineral interest.

Overburden thickness proved to be considerable. The greatest thicknesses of overburden penetrated were 200 ft (60 m) in GRC-10 (bedrock not reached due to insufficient rods), 170 ft (52 m) in GRC-15 (hole abandoned) and 177 ft (54 m) in GRC-20 (serpentinite bedrock reached) (Figure 3). All three of these holes were drilled within the trace of the Pinchi fault zone.

Some selected drill cross sections are shown in Figures 4a-4c. Sample characteristics as observed during the drill program are consistent with a dominantly lacustrine/fluvio-glacial stratigraphy and, accordingly, the sections have been interpreted in that manner. Widespread and locally thick gravel accumulations occur commonly resting directly on bedrock. This would seem to preclude the underlying bedrock from being a potential source of the nearby mineralized boulder even if it were argued that the drill-hole spacing is not tight enough to adequately test directly for a bedrock source. Nowhere was a basal lodgement till encountered.

7.2 Analytical Data

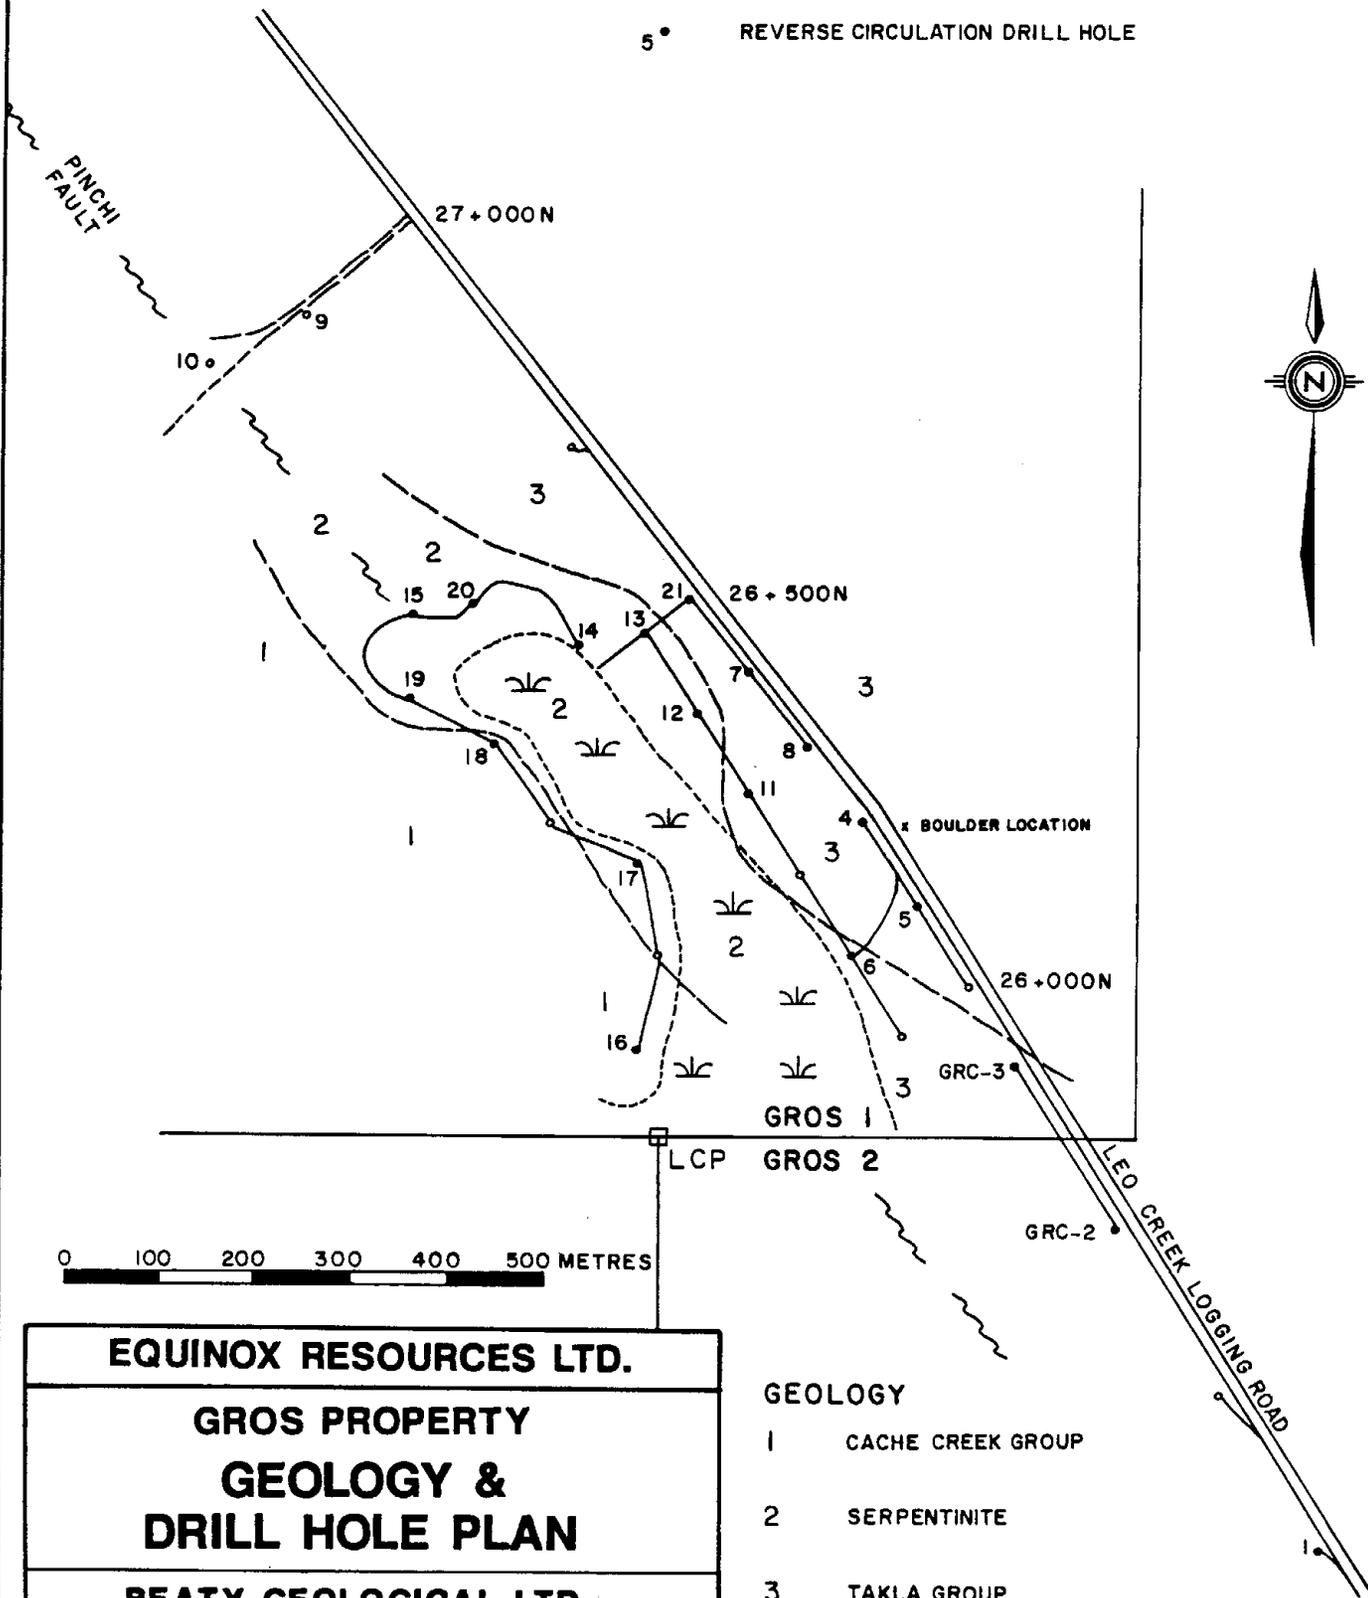

Geochemical results for gold and arsenic are presented in Appendix III. The samples analyzed include:

- (1) All 14 bedrock samples and all 14 basal overburden samples.
- (2) All 12 overburden samples in GRC-4, the closest hole to the site of the gold-bearing boulder.

All the overburden samples, 26 in total, were split into three fractions +20 mesh, -20 +100 mesh and -100 mesh to generate 78 subsamples for analysis.

The data indicate only one anomalous overburden sample in both gold and arsenic, the -100 mesh GRC-12 basal sample (90-95 ft), 23 ppb and 30 ppm respectively. The anomalies are of low order. The sampled zone comprises alternating bands of silt, sand and gravel. The next best gold contents are one at 6 ppb and two at 5 ppb, all of which are subanomalous. There are no anomalous bedrock samples, the highest result being 2 ppb Au and 12 ppm As in separate samples.

8.0 DISCUSSION

In general, the results are disappointing although perhaps it would have been too much to expect immediate success in the very first attempt on a project such as this. At any rate, there are some points that merit mention regarding the results and their implications.

- (1) Reverse circulation is an effective drilling method in areas of heavy overburden as encountered along the Pinchi fault. In particular, the equipment used in this contract is recommended for any future overburden drilling on the project. In that event, at least 300 feet (90 m) of drill rods should be on hand for penetrating especially thick cover.
- (2) The single anomalous sample (23 ppb Au, 30 ppm As) is not considered significant due to:
 - (a) the low order of the anomaly,
 - (b) the fluvio-lacustrine nature of the sample i.e. the source area of the material could be very remote.
- (3) The drill program has eliminated the possibility of a local source for the gold-bearing boulder.
- (4) If the provenance of the mineralized boulder is indeed the Pinchi fault (as seems likely) then there is a choice between exploring the fault either to the north or the south of the Gros property (or both). Exploration to the north is favoured for the following reasons:

- (a) the glacial movement was from the north (more or less),
- (b) glacial drift to the south is expected to be fluvio-lacustrine in nature and, hence, a mineralized source under such a cover does not seem likely; to the north, on the other hand, the edge of the late glacial lake known to have once existed in the region should be encountered in a short distance and true glacial tills might be expected beyond that point - these could be prospected more effectively by geochemistry and boulder searches.
- (5) No further analytical work on the samples from the 1986 drilling is thought worthwhile given their essentially lacustrine or fluvial nature.

9.0 RECOMMENDATIONS FOR FUTURE WORK

The following program is recommended to be undertaken over the 15 kilometers or so of extent of the entire claim block to the north of the Gros claims along the Pinchi Fault.

- | | | |
|-----|---|---|
| (1) | Soil sampling - 100 m x 200 m grid
8 samples/line x 5 lines/km x 15 km = 825 samples
analytical costs - 600 samples x \$8.00 | \$ 4,800 |
| (2) | Prospecting (boulder search)
say 100 samples
analytical costs - 100 x \$8.00 | \$ 800 |
| (3) | Ground magnetics (selected areas)
150 line km at 6 km/day at \$30/day | \$ 2,000 |
| (4) | Pitting, bulldozer (road access, trenching) | \$ 3,000 |
| (5) | Reverse circulation drilling
mob-demob
800 m (2625 ft) at \$35.00
analytical-250 samples at \$8.00 | \$ 2,000
28,000
<u>2,000</u> \$32,000 |
| (6) | Staff
1 geologist-75 days @ \$150/day
1 field technician-75 days @
\$100/day
2 field assistants-100 man days
@ \$80/day
Statutory contributions (30%) | \$11,250
7,500
8,000
<u>8,025</u> \$34,775 |

(7) Field Costs		
Accommodation, meals, etc. - 350 man days @ \$50.	\$12,500	
Vehicles-2 (2.5 mos. @ \$1500/mo)	7,500	
Fuel, maintenance, spares	<u>2,625</u>	\$ <u>22,625</u>
TOTAL		\$100,000

The soil sampling budget is considered an upper limit in that the program could be reduced if field observations of the nature of the overburden suggested unfavourable sampling conditions i.e. fluvio-glacial/lacustrine material. Excess funds could be directed toward any of ground magnetics, bulldozer time and reverse circulation drilling.

Ground magnetics assumes a 100 x 200 m grid over a 2 x 15 km area. The purpose of the survey would be to define positive magnetic features in the Pinchi fault likely to be caused by ultramafic bodies.

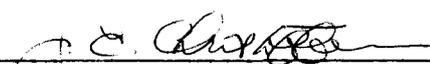

Reverse circulation drilling would be employed to test overburden/bedrock anomalies defined by geochemistry and/or geophysics. On the basis of the Gros property, the meterage should be sufficient to drill 25 - 30 holes.

CERTIFICATE OF QUALIFICATIONS

I, JAN ERIK CHRISTOFFERSON, hereby certify that:

1. I am a practicing Geological Engineer with offices at 500 - 576 Seymour Street, Vancouver, British Columbia.
2. I am a graduate of the University of Toronto, B.Sc. (1968), Geological Engineering.
3. I have practiced mining exploration for twenty-one years, throughout the world, including eighteen years with AMAX Exploration Inc.
4. I have recently written examinations required for membership in the Association of Professional Engineers of the Province of British Columbia.
5. I have no interest, directly or indirectly, in the properties or securities of Equinox Resources Ltd.
6. I personally supervised and largely carried out the field work on which this report is based.

DATED at Vancouver, British Columbia, this 30th day of September, 1986.

J.E. CHRISTOFFERSON, B.Sc.

APPENDIX III

Analytical Procedure

Acme Analytical

1. Sample Preparation

- a) Overburden samples were split in half and dried before screening at +20 mesh, -20 +100 mesh and -100 mesh. Subsamples of the three size fractions were ground to -100 mesh, if required, for geochemical analysis.
- b) Bedrock samples were split in half and dried. A subsample was taken and ground to -100 mesh for analysis.

2. Geochemical Analyses

- a) Gold - A 10-gram sample is ignited for four hours at 600 C followed by digestion in 30 ml of aqua regia for one hour at 95 C. The sample is made up to 100 ml with water. Five ml of M18K is used to extract Au from 75 ml of clear solution. Au is determined by graphite-furnace AA to 1 ppb detection.
- b) Arsenic - A 0.5 gram sample is digested with 3 ml of aqua regia at 95 C for one hour and is made up to 10 ml with water. As is determined by ICP emission spectrometer to 1 ppm detection.
