UTOPIA PROPERTY

Atlin Mining Division

NTS 104 N/12E

SUMMARY

The Utopia lode gold prospect is located 8 kilometres east of Atlin in northwestern British Columbia. During 1986, a work programme consisting of VLF-EM and proton precession magnetometer surveys were carried out on the property to define the margins of the magnetometer 'highs' which are thought to be ultramafic bodies. Six diamond drill holes were put in along these margins.

Recent drilling on adjacent properties have indicated the presence of gold mineralization in a quartz stockwork within a carbonatized margin to an ultramafic body. Gallant's drill programme has indicated a good potential for discovering stockwork-type gold occurrences on the Utopia property along the Pine Creek fault valley.

GALLANT GOLD MINES LTD.**UTOPIA PROPERTY****Atlin Mining Division****1. INTRODUCTION**

The Utopia property is a lode gold prospect located in the heart of the historic Atlin placer gold camp in northwestern British Columbia (Fig. 1). The property was initially staked in July 1984 by Gallant Gold Mines Ltd.

In 1986, a work programme consisting of diamond drilling, VLF-EM and proton precession magnetometer surveys were carried out over the property. A three-man crew working out of the town of Atlin, completed this work during the period June 2 to December 5, 1986. The programme was supervised by Mark Management project geologist L. Dandy under the guidance of A.G. Troup, P.Eng., of Archean Engineering Ltd.

1.1 LOCATION AND ACCESS

The Utopia gold property located approximately 8 kilometres east of Atlin, covers an area of 4 square kilometres over the Pine Creek valley. The claim is centred at latitude $59^{\circ}33'$ and longitude $133^{\circ}26'$ on NTS map sheet 104 N/12.

GALLANT GOLD MINES LTD.

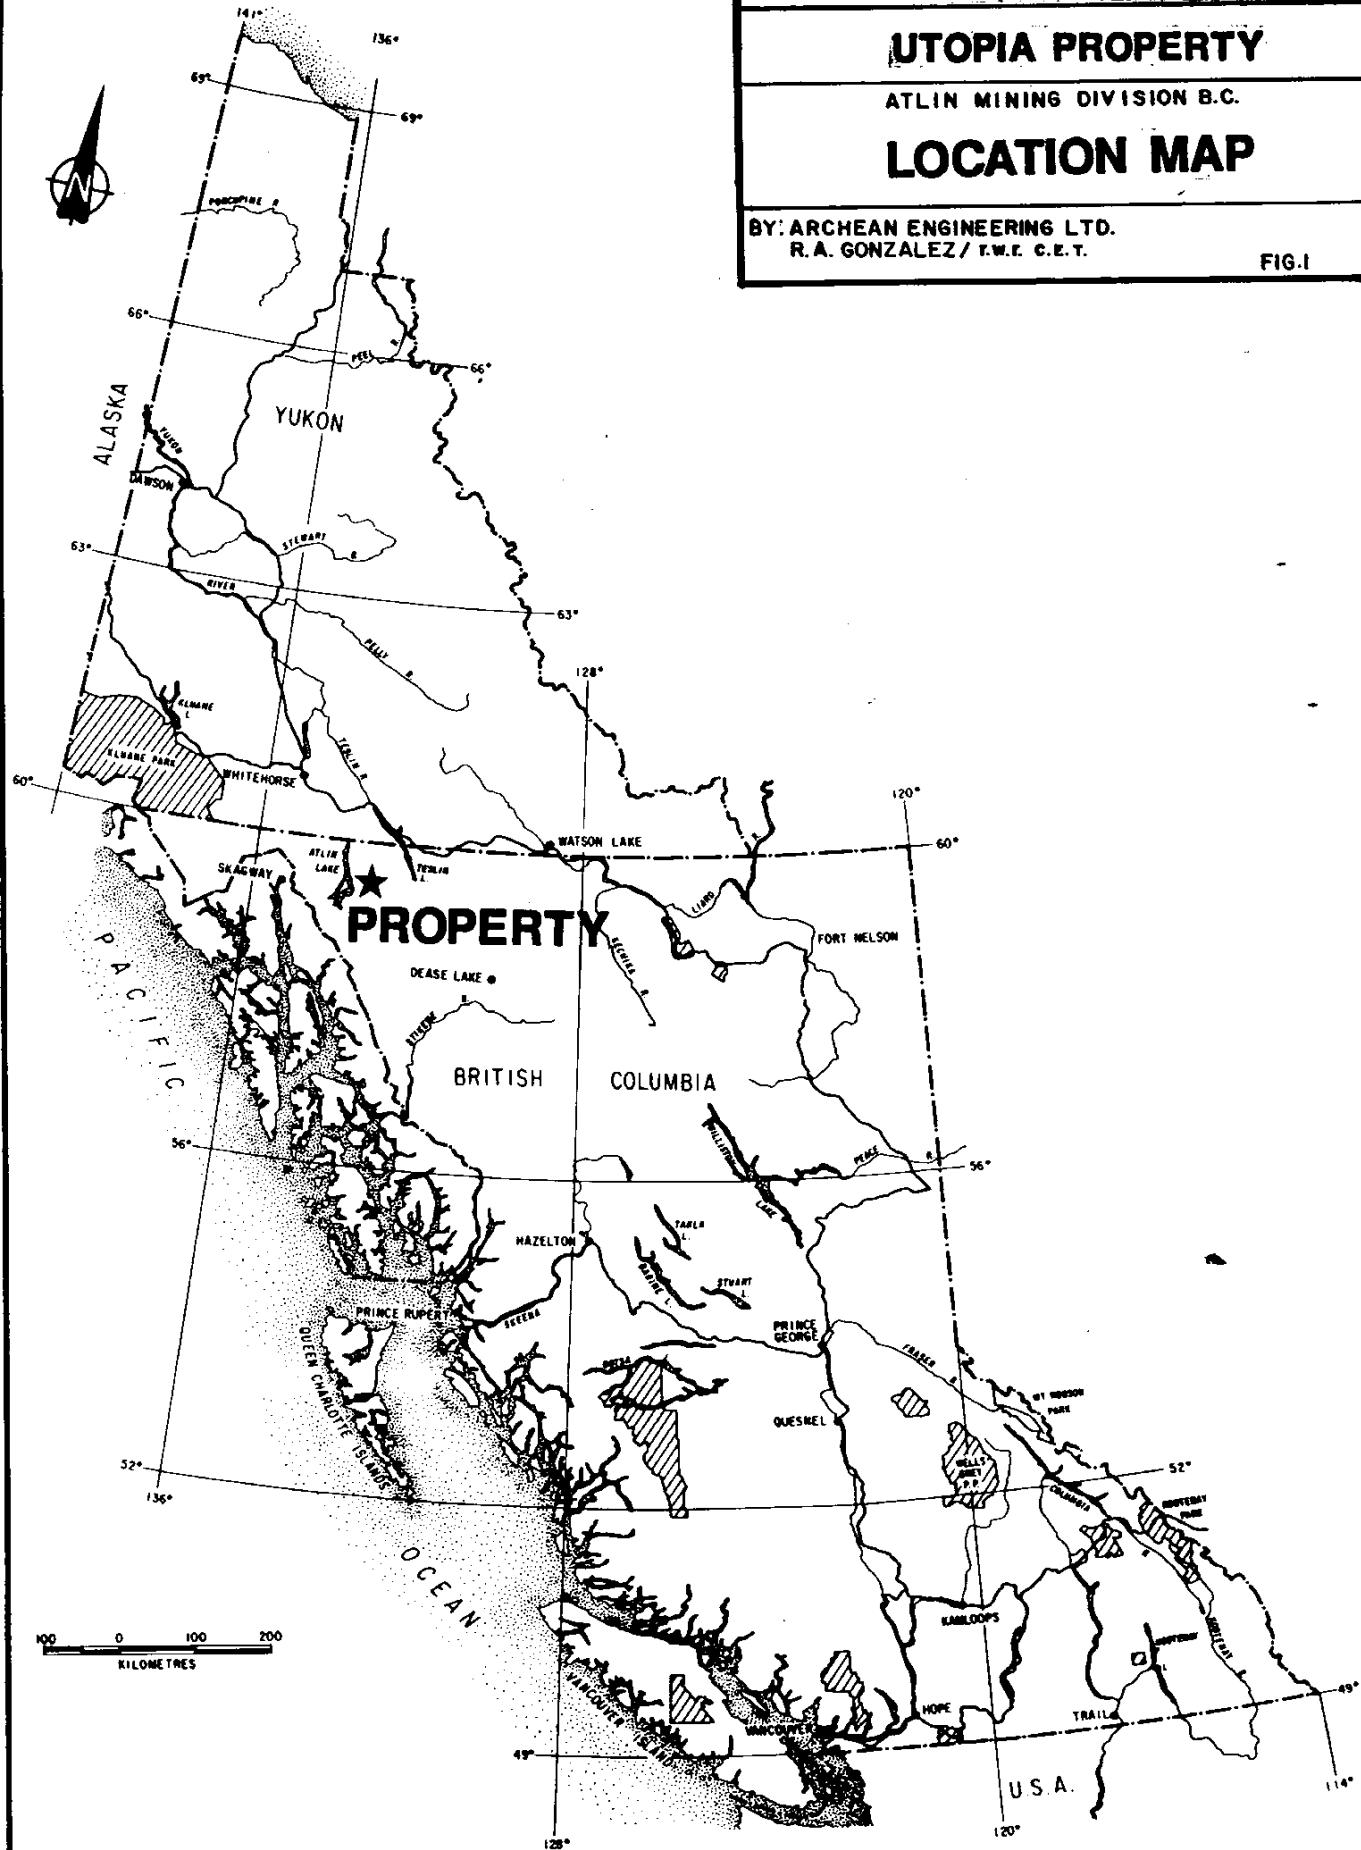

UTOPIA PROPERTY

ATLIN MINING DIVISION B.C.

LOCATION MAP

BY: ARCHEAN ENGINEERING LTD.
R.A. GONZALEZ / F.W.E. C.E.T.

FIG. I

Atlin may be reached by car from Jakes Corner on the Alaska Highway (Mile 865), a distance of about 100 kilometres, along Highway 7. The distance from Jakes Corner to the major northern city of Whitehorse is 84 kilometres along the Alaska Highway, which is paved over this entire length. Whitehorse is served with several flights a day from other major centres in Canada and Alaska.

Excellent access to the claims is provided by an all weather gravel road that connects Atlin and Surprise Lake.

1.2 PHYSIOGRAPHY, VEGETATION AND CLIMATE

The Atlin area is located just east of the Coast Mountains on the Teslin Plateau. The town of Atlin lies on the east shore of Atlin Lake, the largest natural lake in British Columbia, at an elevation of 2,200 feet. The topography is moderately rugged with slopes of up to 30° rising from the Pine Creek valley floor at an elevation of 3,000 feet to mountains well over 6,000 feet. The immediate area of the property consists of short steep hills and wide, U-shaped valleys striking northeast and northwest. Glaciers occupied many of the valleys in Pleistocene time and deposited up to 300 feet of glaciofluvial till during their retreat. Till cover is thin or non-existent above the valley floor, giving way to felsenmeer and outcrop at higher elevations. The tree line is at approximately 4,500 feet on north facing slopes and 5,000 feet on south-facing slopes. Below

4,500 feet, the valleys are forested with lodgepole pine, black spruce, aspen and dwarf birch. Mountain alder and willow grow near streams with stunted buckbrush covering the hills above tree line.

Atlin enjoys a pleasant summer climate with temperatures averaging 20°C and little precipitation. Winter temperatures average -15°C in January with moderate snowfall. Total annual precipitation has been measured at 279.4 millimetres of moisture. "Winter" conditions can be expected from October to April.

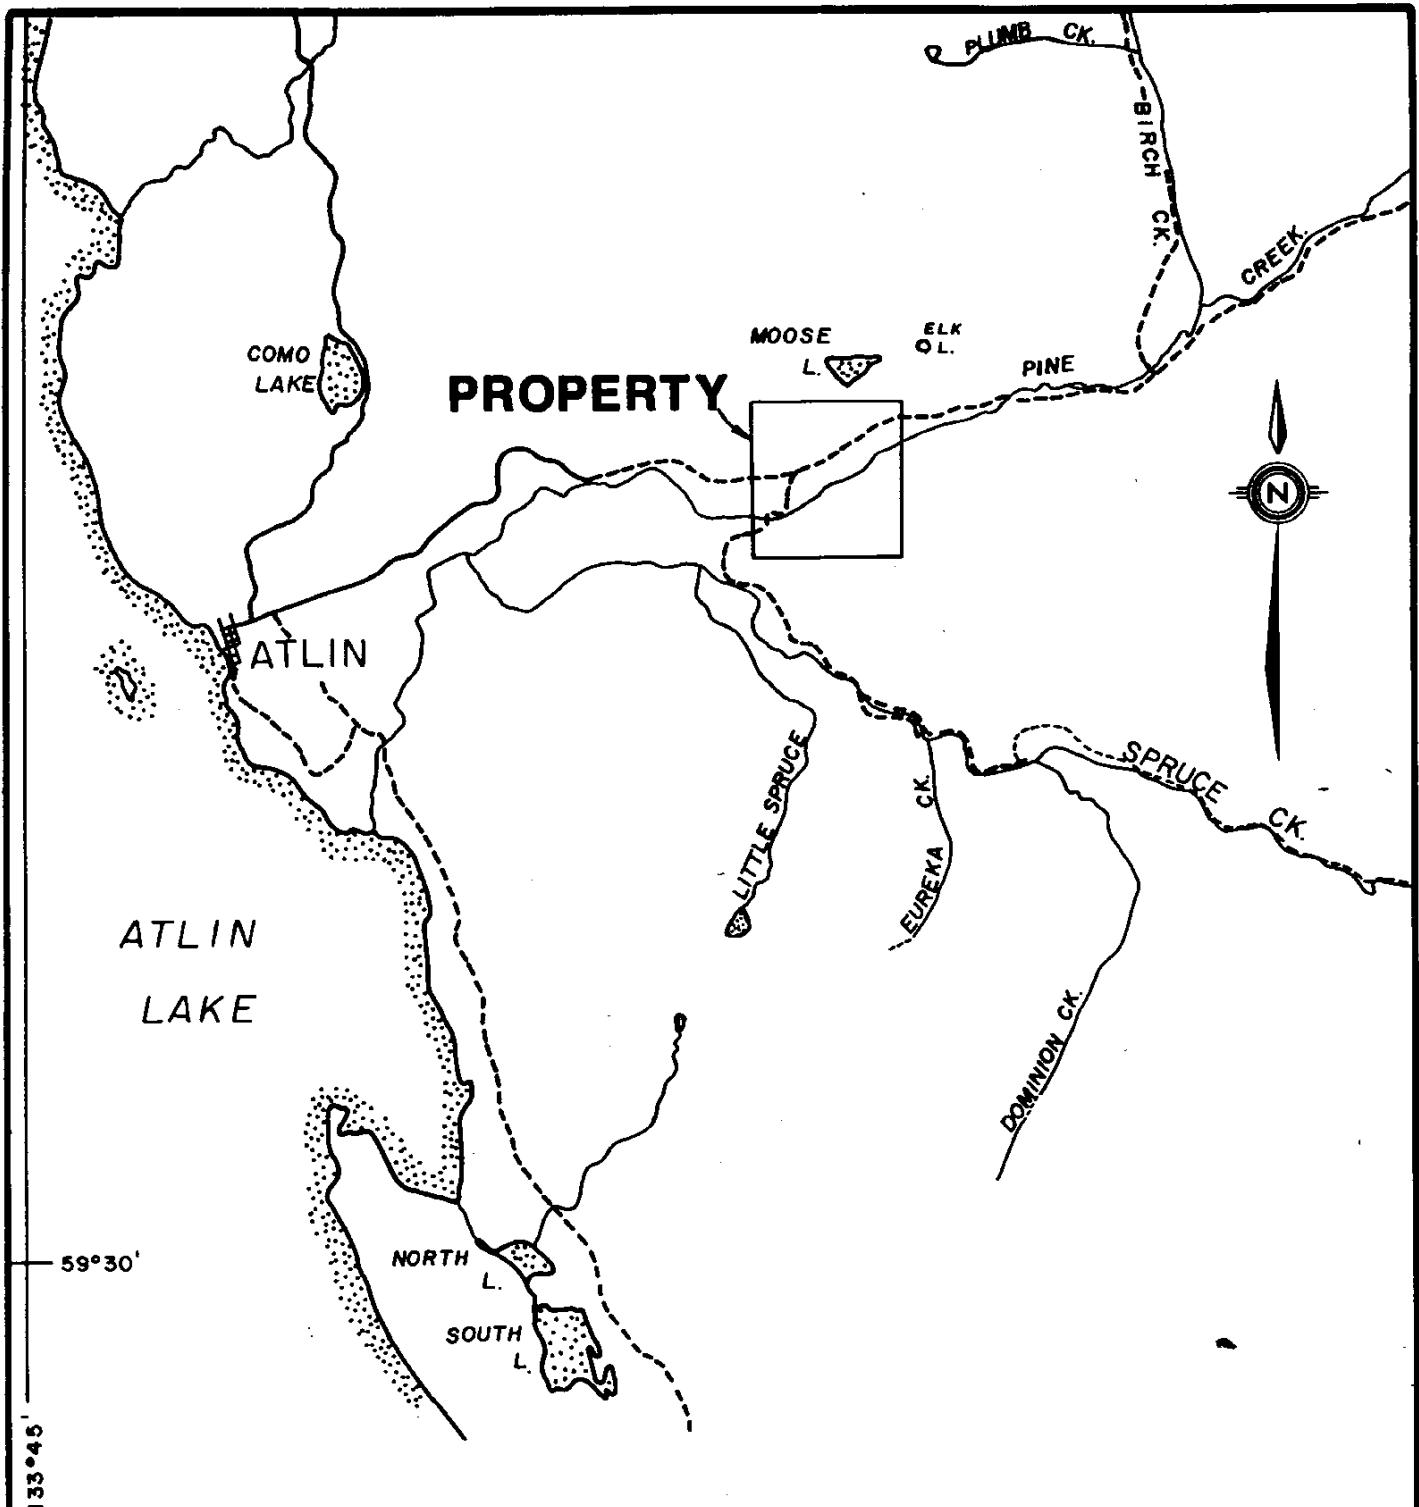

1.3 CLAIM INFORMATION

The property is located in the Atlin Mining Division and consists of 1 modified grid claim totalling 16 units (Fig. 2). The claim is owned by Gallant Gold Mines Ltd. of Vancouver, B.C. Claim information is listed in Table 1.

FIG. 2

1.4 HISTORY

Gold was first discovered in the Atlin area in 1897 by Fritz Miller while en route to Dawson. The first workings were on Pine Creek and by the end of 1898, more than 3,000 people were camped in the Atlin area. Only 8 creeks - Spruce, Pine, Birch, Boulder, Ruby, Otter, Wright and McKee - have been important producers in the Atlin camp. Gold production from these creeks in the period 1898 to 1946 is listed in Table 2. By far the most important producer was Spruce Creek with a reported total of well over 260,000 ounces of placer gold through 1946. Almost all the gold was recovered from a Tertiary channel which appeared as a claybound orange-red gravel about three metres thick overlying bedrock. The channel was worked more or less progressively upstream from west to east for a distance of five and a half kilometres. The eastern limit of the worked channel is located at the old Nolan Mine at the confluence of Spruce and Dominion Creeks. By 1957, the workings had been advanced underground a further 1,266 metres upstream. Gravels worked underground are reported to have averaged 0.65 ounces of gold to the cubic yard.

Gold-bearing quartz veins were first discovered in the Atlin area in 1899 and by 1905 most of the known showings had been discovered. Although the original showings have been repeatedly worked and re-examined there is no record of regional exploration for lode mineralization since 1905.

In 1981, Yukon Revenue Mines Ltd. acquired and re-examined the old Lakeview property. Work done by Yukon Revenue showed low-grade gold values over an extensive but delicate quartz stockwork in carbonatized and silicified andesite adjacent to a serpentinite intrusive.

In 1986, Homestake aquired the old Yellow Jacket claims along Pine Creek, adjacent to the Utopia property. Their drilling has indicated several intersections of up to 10 feet grading 0.5 oz/T Au or better. The gold values are coming from a quartz stockwork with up to 1/2% pyrite in a carbonatized, talcose ultramafic.

The discovery by Yukon Revenue Mines Ltd. in the vicinity of major placer gold producing streams prompted Gallant Gold Mines Ltd. to stake the Utopia property. The similarity to the geology found in Homestake's drill holes indicates the potential for economic gold mineralization on Gallant's property.

TABLE 2 (from Holland, 1950)**Gold Recovery from Productive Creeks, Atlin Area, 1898-1946**

Stream Name	Ounces of Gold Produced
Spruce Creek	262,603
Pine Creek	138,144
Boulder Creek	67,811

McKee Creek	46,953
Otter Creek	20,113
Wright Creek	14,729
Birch Creek	12,898
All Others (21 creeks)	15,624

1.5 WORK DONE BY GALLANT GOLD MINES LTD. IN 1986

The following field work was completed on the Utopia property by Gallant Gold Mines Ltd. during the period June 2 to December 5, 1986:

- 1) Proton Precession Magnetometer survey over the entire Utopia claim.

- 2) VLF-EM survey over selected areas of the Utopia claim in an attempt to define areas of sulfide rich rocks.
- 3) Diamond drilling of 2,630 feet (801.6 m) of 'NQ' core in 6 holes on the Utopia mineral claim.

2. GEOLOGY

2.1 REGIONAL GEOLOGY

Geologic mapping of this area was undertaken in 1951-55 by J.D. Aitken of the Geological Survey of Canada (GSC) and compiled as Map 1082A (Fig. 3). In 1966-68, J.W.H. Monger, also of the GSC, selectively mapped the Atlin area and published his findings in GSC Paper 74-47.

The Atlin region is located in a eugeosynclinal area composed of three distinct northwest striking tectonic belts; the St. Elias and Insular Belt, Coast and Cascades Belt and Intermontane Belt. The rocks of the area belong to the Atlin Terrane, which represents an independent tectonic entity of the oceanic sequence of the Intermontane Belt in the Canadian Cordillera. The Atlin Terrane consists of upper Paleozoic age radiolarian cherts, pelites, carbonates, volcanics and ultramafics. These rocks are intruded by Mesozoic granite, alaskite and quartz monzonite. The youngest rocks of the Atlin Terrane are composed of Tertiary and Quaternary

volcanics. Till deposited by receding Pleistocene glaciers extensively covers the valleys.

The Atlin Terrane is bounded on the northeast by a northwest striking vertical fault and on the southwest by a northwest striking reverse fault. Structurally, the terrane is characterized by compressional deformation which is similar in style and trend to the southwest bounding faults (Monger, 1975). Minor fold axes generally strike northwest or trend southwest.

2.2 PROPERTY GEOLOGY

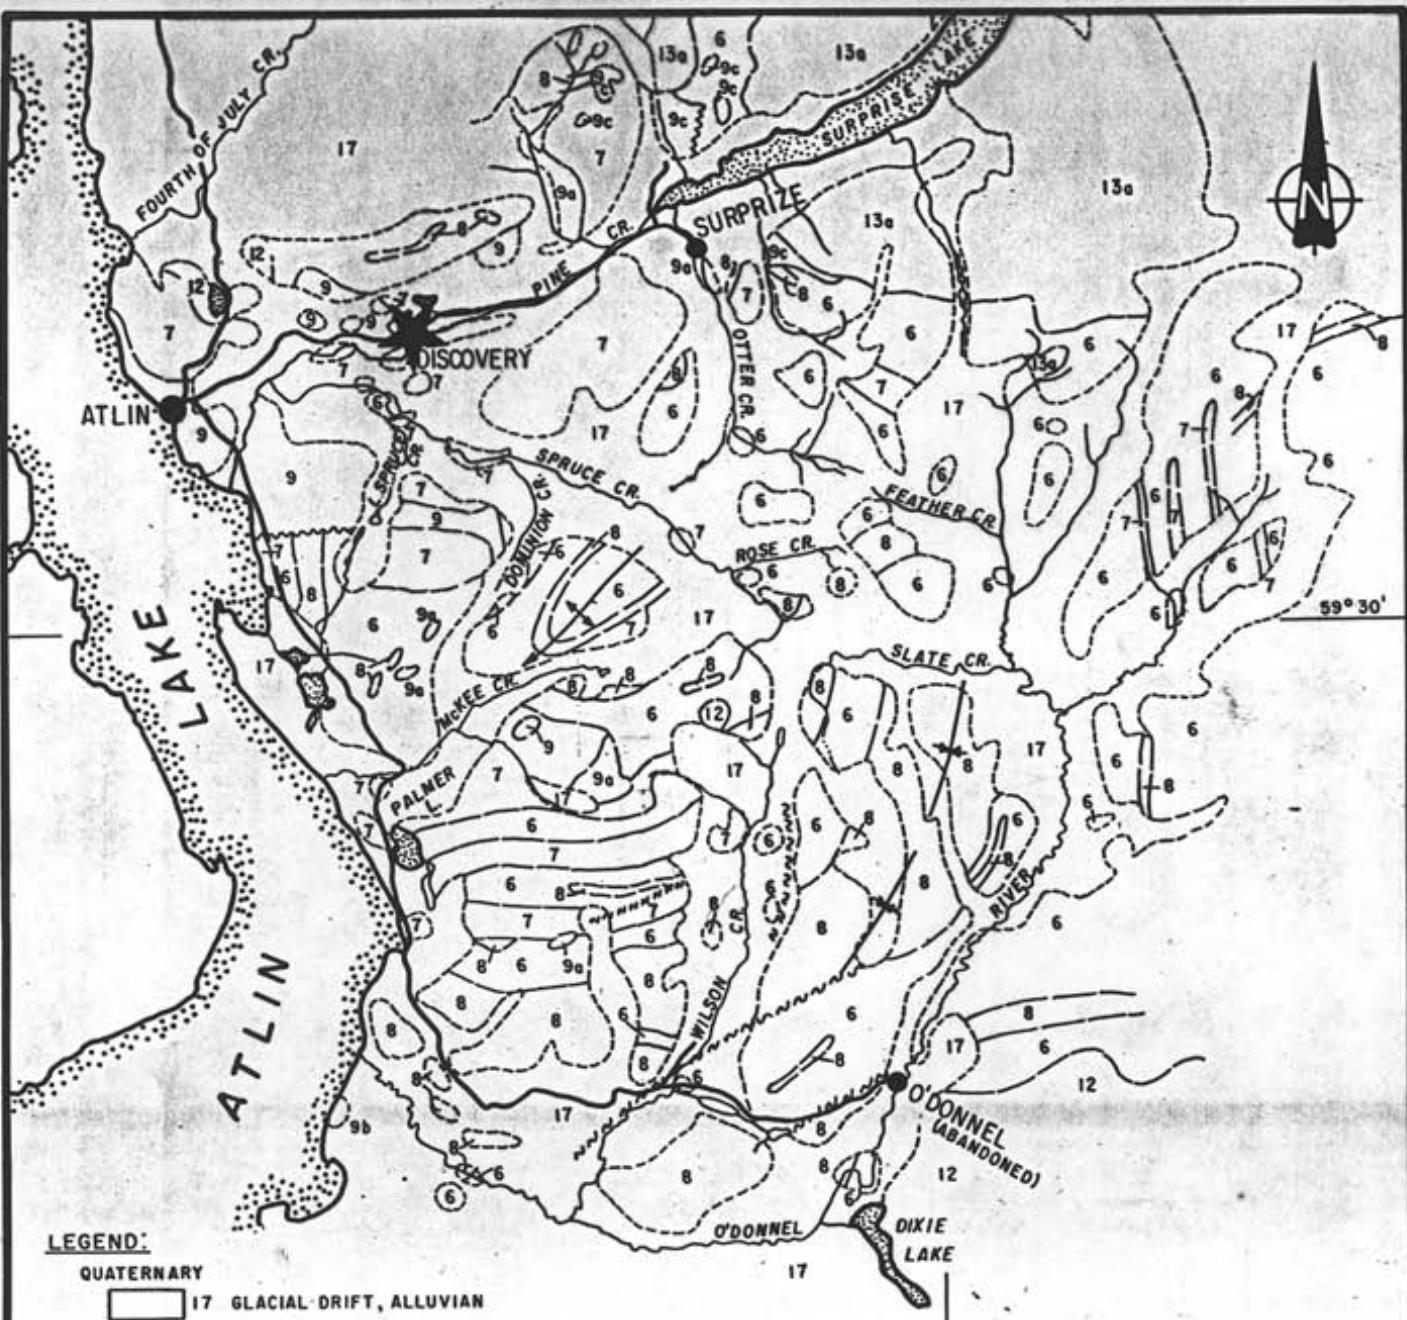

Outcrop exposure accounts for less than 10% of the surface area on the property. Felsenmeer is present in areas of no outcrop and is assumed to be close to outcrop. Till covers the valleys below 4,300 feet elevation.

The Utopia property is underlain by Cache Creek Group metasediments and basic volcanics intruded by Pennsylvanian and Permian age ultramafics and minor amounts of Tertiary olivine basalt.

The Cache Creek Group is of Pennsylvanian and Permian age and consists of limestone, chert, argillite and andesite (greenstone). Monger (1975) classifies the limestone and chert as forming part of the Kedahda Formation and the andesite as part of the Nakina

Formation. The andesite is typically drab grey-green in colour, siliceous, sometimes weakly carbonatized and contains up to 1% primary pyrite. The carbonatized ultramafic and carbonatized andesite are often difficult to distinguish because of their intensely altered and indistinct contacts. The fetid limestone is ash grey in colour and contains fossil fragments believed to be crinoids. The dark grey to black coloured chert is commonly interbedded with cherty or graphitic argillite.

The Pennsylvanian and Permian ultramafics are part of the Atlin Intrusions and consist of serpentinite, peridotite and minor mafic dykes which have undergone varying intensities of carbonatization, serpentinization and steatization. Alteration of the ultramafic is most intense along shear zones where it occurs as a recessive unit. The carbonatized ultramafic is characterized by its orange-brown colour, due to the surface weathering of siderite, and the presence of mariposite (a chromium high-silica mica). Other carbonate minerals present include ankerite, magnesite, dolomite and calcite. Networks of quartz veinlets found in the carbonatized ultramafic are a result of silica being liberated during the alteration of serpentinite to siderite or magnesite. Talcose ultramafics occur where much shearing and hydrothermal activity has taken place. The intrusive nature of the ultramafic suggests that sills and dykes of it pinch and swell in thickness. Weakly magnetic Tertiary olivine basalt dykes crosscut all the units.

R.A.GONZALEZ / r.w.r. FIGURE 3

Stratigraphically, from top to bottom, the units are as follows: olivine basalt, andesite, carbonatized ultramafic, ultramafic, chert interbedded with argillite, and limestone. Locally pods of limestone are seen to lie stratigraphically above the ultramafic and below the chert. This incongruity is explained by the rafting up of limestone pods by the ultramafic as it intruded upwards through the limestone. The true thickness of each unit is uncertain. The lower contact of the limestone was not mapped, making a determination of its thickness impossible. The chert horizon appears to vary dramatically in thickness; anywhere from a metre to tens of metres thick. Due to erosion, the thickness of the andesite is unknown although it is believed to exist only as a thin capping.

Major shear and fracture directions in this area are known to be  $030^{\circ}$ ,  $060^{\circ}$  and  $170^{\circ}$ . Hidden shears/faults may occur parallel to or underlie many of the placer gold producing creeks. This is especially true of the Pine Creek/Surprise Lake linear which strikes  $060^{\circ}$ . The valleys of Birch, Boulder, Otter and Ruby Creeks, which all strike approximately  $170^{\circ}$ , are thought to be tension gashes or fractures related to the Pine Creek/Surprise Lake linear. These linears are believed to be related to gold mineralization, as many of the lode showings and all the auriferous veins in the locality have similar orientations.

### 3. DIAMOND DRILLING

A diamond drilling programme consisting of 6 'NQ' size holes totalling 2,630 feet was carried out by Phil's Diamond Drilling Ltd. and Arctic Diamond Drilling Ltd. during August to November 1986 (Table 3, Fig. 4). Dip tests were taken at the collar and at the bottom of each hole. Drill core is presently stored in Atlin.

TABLE 3

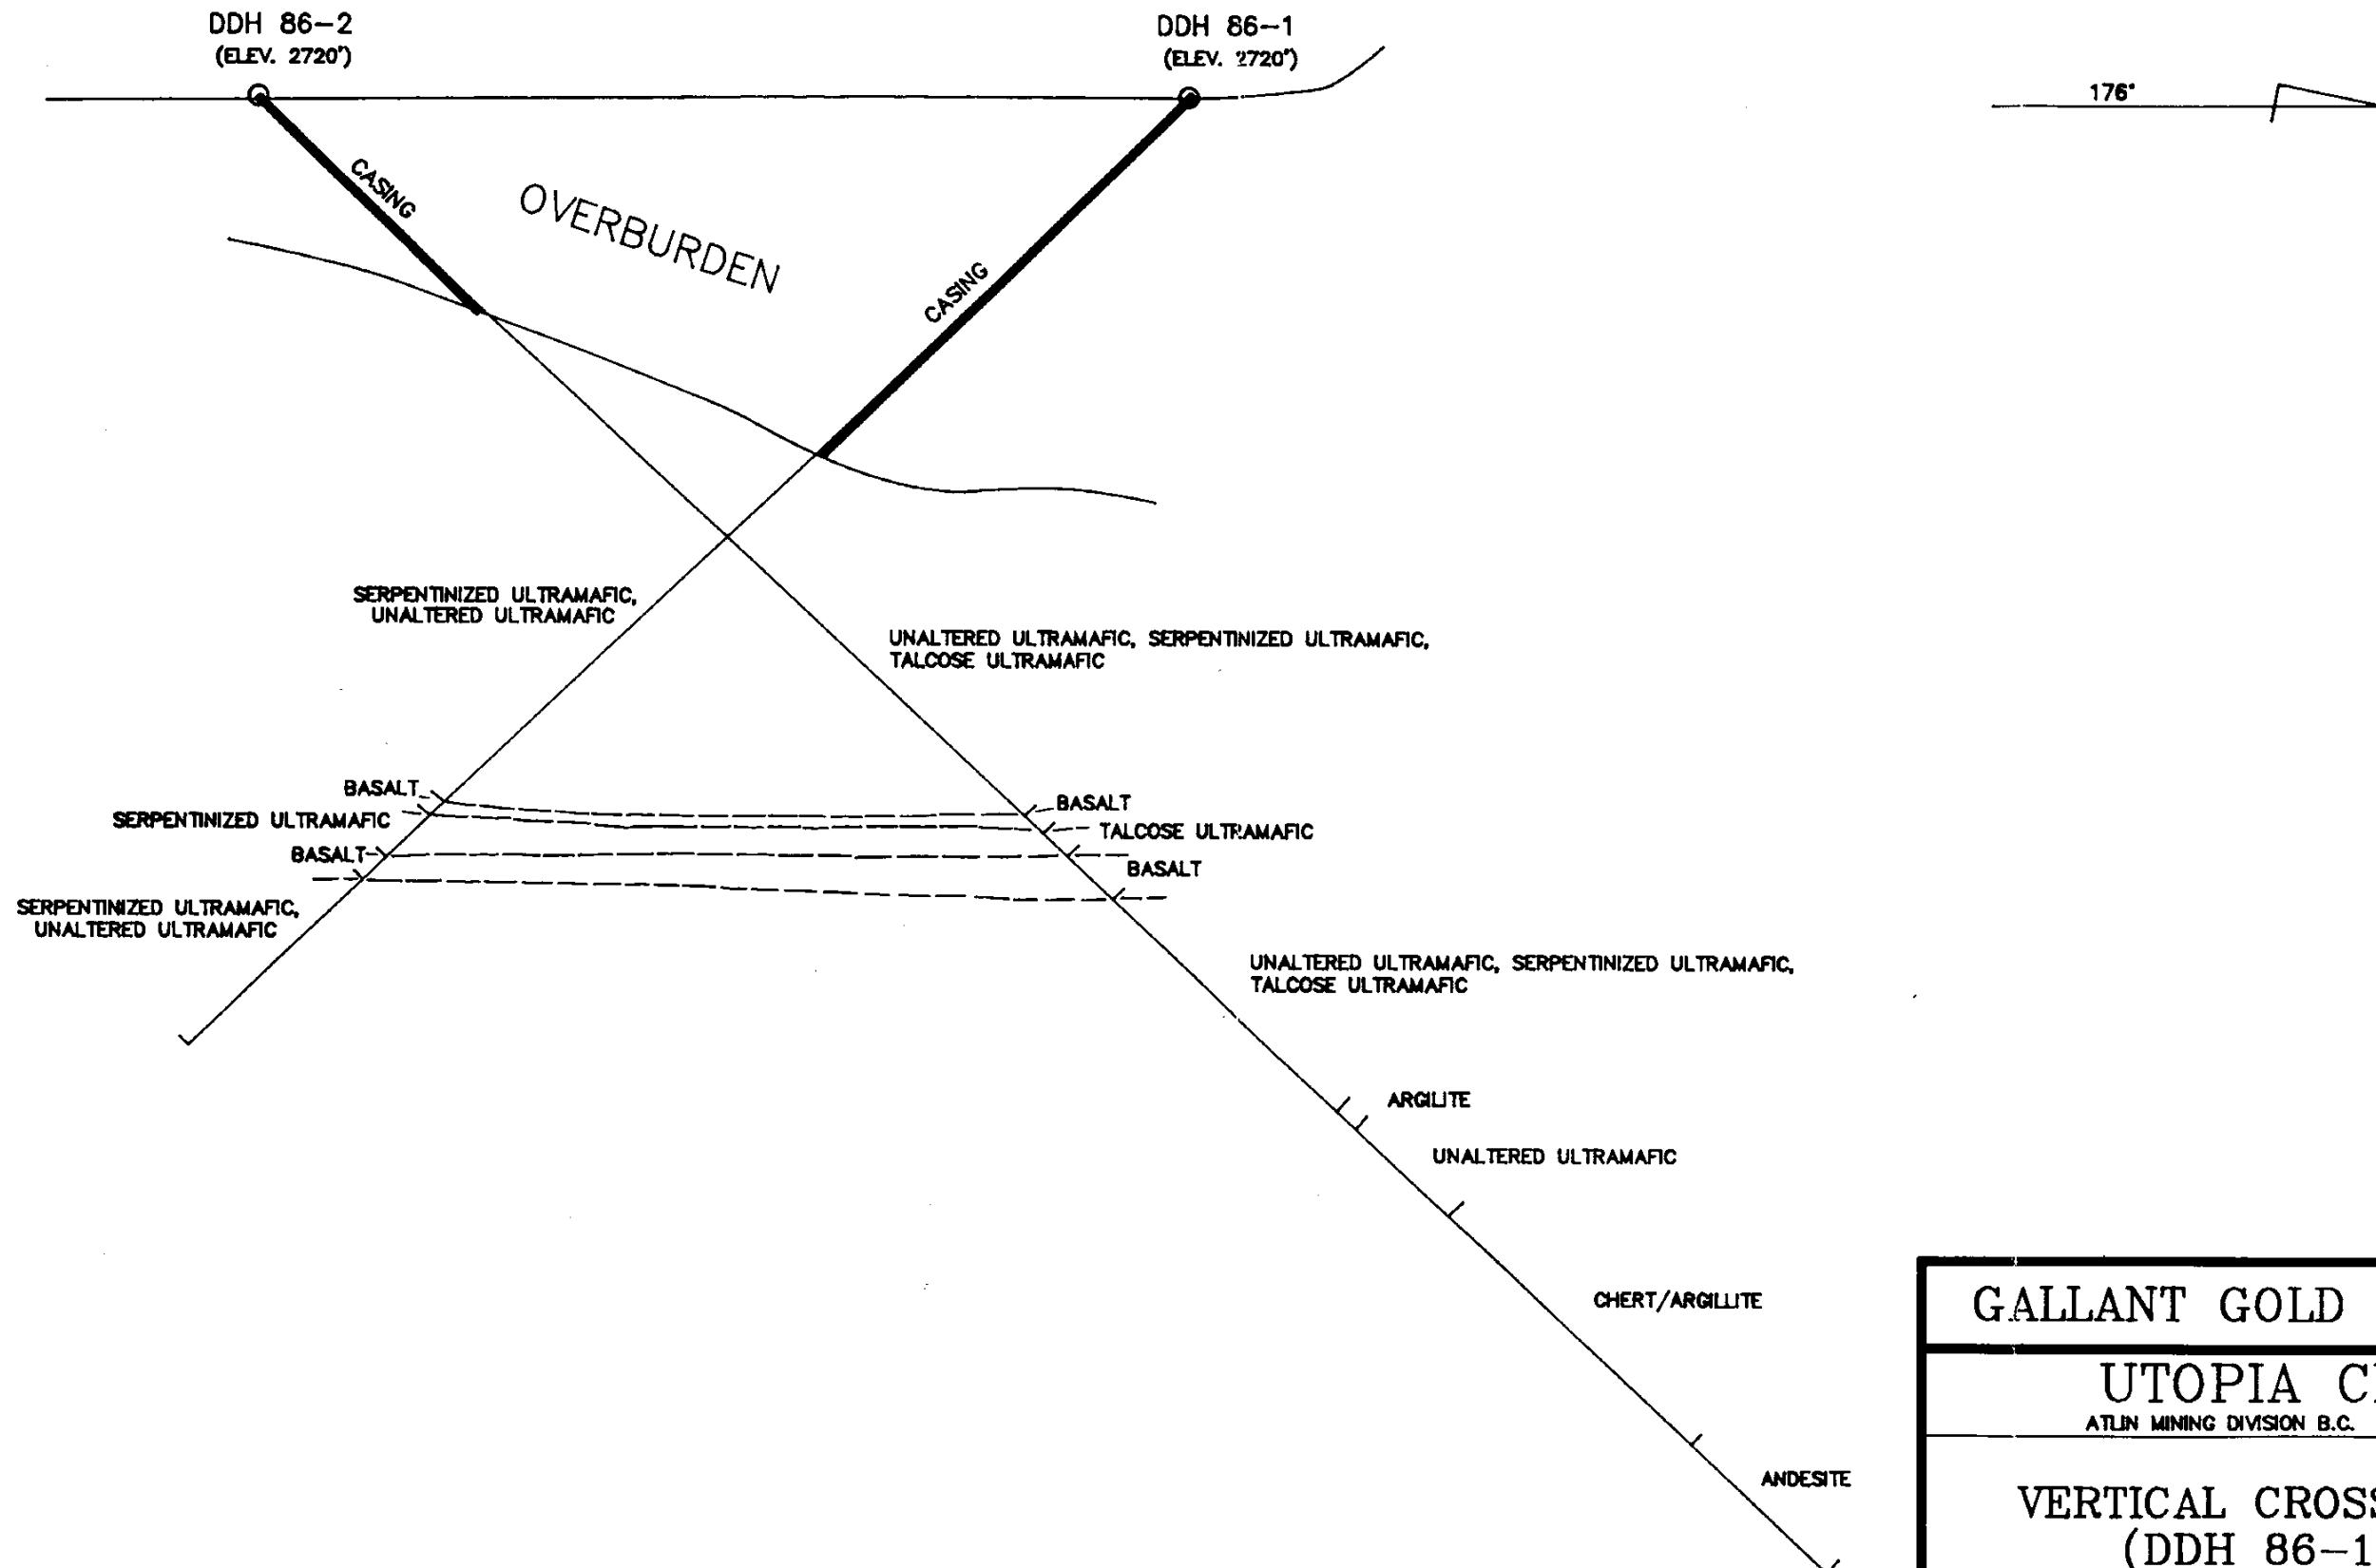

## DIAMOND DRILL HOLE DATA

| Drill Hole   | Location | Azimuth | Dip(collar) | Length(ft.) |
|--------------|----------|---------|-------------|-------------|

| 6            | Utopia   | 000°    | -45°        | 254         |

### 3.1 DRILL HOLE GEOLOGY

Drill holes 1 to 5 were drilled to test the edges of magnetometer highs which are believed to be ultramafic intrusive bodies. The edges of these ultramafic bodies are commonly altered by carbonatization and/or silicification. Other drill programmes in this area have shown that where pyrite is present in a quartz stockwork system within a carbonatized ultramafic there is an excellent potential for gold mineralization. Drill hole 6 was placed along strike from hole 3 which had the best section of quartz stockwork, therefore the best chance for gold mineralization. Two additional drill holes were also attempted along strike from holes 3 and 6 but were unsuccessful due to loose, deep overburden.

Rock units encountered in the drill core consisted primarily of ultramafics (serpentinized, carbonatized, silicified and unaltered), chert/argillite, andesite and an intrusive sub-volcanic with large feldspar phenocrysts. Most of the core is intensely fractured, sheared and incompetent, creating drilling and drill hole correlation problems. Although the stratigraphy appears somewhat complicated in drill core, due to intense shearing and alteration it is believed that the stratigraphic section described earlier in Section 2.2 holds true (Fig. 5 and 6).

### **3.2 MINERALIZATION**

Assay data is given in the drill logs (see appendix). The highest assay was 0.009 oz/ton gold over 10 feet and 8.6 ppm silver over 7.5 feet in 86-3. No economic gold values over mineable widths were encountered in any of the drill holes. Other metallic sulphides seen were galena and chromite in 86-3, 5 and 6 and pyrite in all the drill holes. Ultramafic with magnetite and chromite is believed to be the cause of the magnetometer high readings and conductive overburden is believed to be the cause of the VLF EM-16 conductors found on the property.

## **4. GEOCHEMISTRY**

### **4.1 DRILL CORE SAMPLING**

#### **4.1.1 SAMPLING AND SAMPLE TREATMENT**

A total of 241 core samples were collected from the six holes drilled on the Utopia claim. The entire length of the core was sampled with average sample width of 5 feet and smaller samples being taken where mineralization or veining was present. The core was logged, split, crushed and riffle split in the field, with samples of .25 to .50 kilograms being sent to Chemex Labs Ltd. in North Vancouver for analysis. In the lab the samples were crushed to minus 100 mesh,

fire assayed for gold and given a 30 element ICP analysis.

#### **4.1.2 PRESENTATION AND DISCUSSION OF RESULTS**

Sample locations, widths, rock types and assay data can be obtained from the drill logs found in the appendix. No significant mineralization was encountered in the core, however, quartz stockworks within carbonatized ultramafics were found. These stockworks have good potential for having spotty gold mineralization concentrated in zones along the strike of this system.

### **5. GEOPHYSICS**

#### **5.1 VLF-EM SURVEY**

##### **5.1.1 INSTRUMENT AND SURVEY TECHNIQUES**

Reconnaissance VLF-EM surveys were carried out over the Utopia Claim using a Geonics EM-16 instrument. A total of 2.7 line kilometres were surveyed with readings taken at 25 metre intervals along north-south lines spaced 200 metres apart. The survey used the submarine transmitting station in Seattle, Washington (Station NLK, 24.8 kHz), with in-phase and quadrature readings taken in a westerly direction ( $235^\circ$ ) to ensure that east dips were indicated as negative

readings by the instrument. The in-phase readings were reduced by using the Fraser Filtering Technique (Fraser, 1969) and contoured.

### **5.1.2 PRESENTATION AND DISCUSSION OF RESULTS**

Results of the survey are shown in Figure 7. In-phase and filtered in-phase readings are shown, with the filtered in-phase readings contoured at 10% contour intervals.

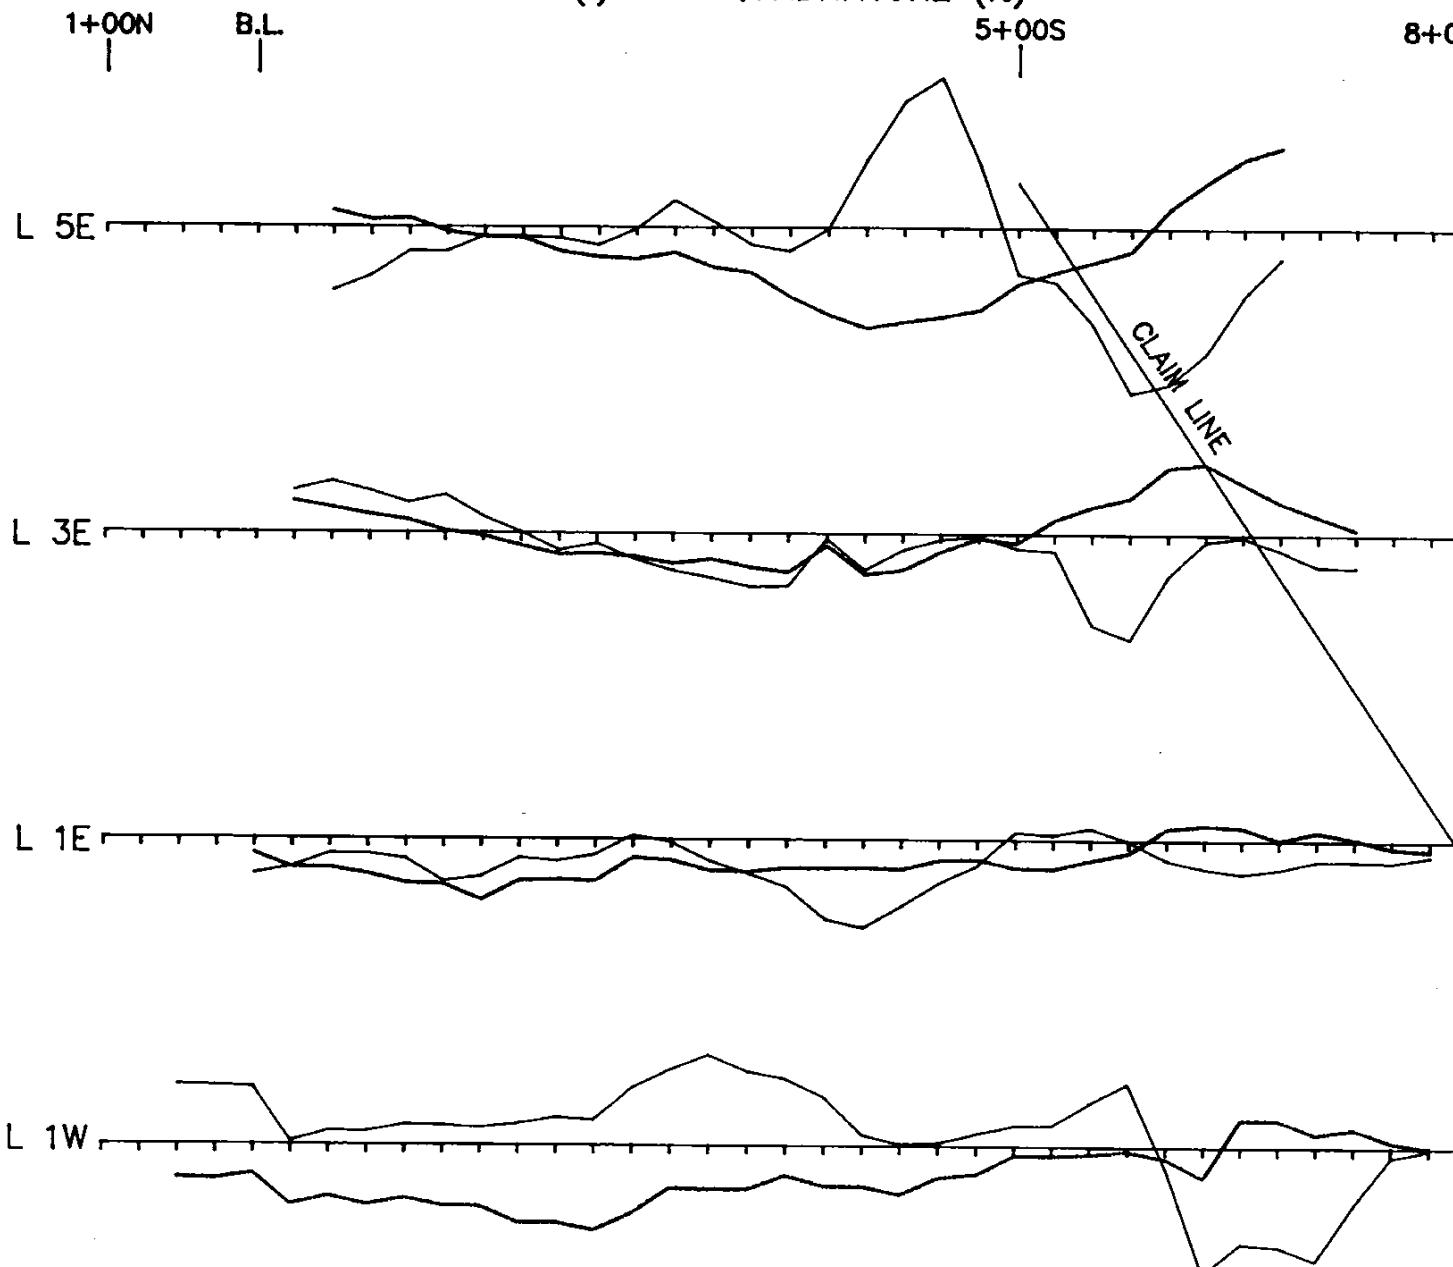

The survey was conducted over an area known to be underlain with a carbonatized ultramafic containing a quartz stockwork. The presence of sulfides in this stockwork is thought to be coincident with gold mineralization. It was hoped that sufficient sulfides would be present in these rocks to give a conductive reading giving further drill targets. A conductor of +29 was found and drill hole 7 was attempted at this location. Overburden in excess of 100 feet was encountered making drilling at this location impossible. This depth of overburden would likely mask any VLF responses from the underlying rocks so it is concluded that the conductor encountered in this location is likely due to conductive overburden rather than to sulfide enrichment in the underlying bedrock.

## 5.2 PROTON PRECESSION MAGNETOMETER SURVEY (total field magnetics)

### 5.2.1 INSTRUMENT AND SURVEY TECHNIQUES

A proton precession magnetometer survey was also carried out over the entire Utpoia claim. A total of 24.3 line kilometres were surveyed using a Geometrics G826 proton magnetometer. A base station was established and readings were corrected for diurnal and day to day variations. Readings were taken in a northerly direction at 25 metre intervals along north-south flagged lines spaced 200 metres apart. The time of day was recorded at each station and later used to correct the field readings.

### 5.2.2 PRESENTATION AND DISCUSSION OF RESULTS

Results of the survey have been contoured and are shown in Figure 7. Readings are in gammas ( $0 = 50,000$  gammas) and have been corrected for diurnal and day to day variations.

The magnetometer readings show a range of values from 57,326 to 60,733 gammas. A prominent east-west striking zone of at least 1,800 metres length, located approximately following the Pine Creek valley and appears to be delineating ultramafics of the Atlin Intrusions. Immediately to the north and south of this magnetic anomaly is carbonatized and silicified ultramafic which shows up as magnetometer

low readings. This survey has delineated favourable geology (i.e. quartz stockwork hosted in altered ultramafics) which was obscured by vegetation and overburden.

## 6. CONCLUSIONS

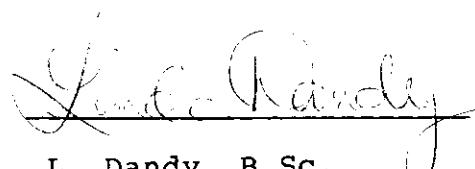

The results of the 1986 programme indicate that the property has potential for the discovery of stockwork-type mineralization along the Pine Creek valley. Important findings of the programme are summarized as follows:

- 1) Geology of the property shows Cache Creek Group rocks intruded by ultramafics of the Atlin Intrusions. Carbonatization and silicification of the ultramafic is extensive and areas of quartz stockwork within this alteration is believed to be associated with the gold mineralization in this area.
- 2) VLF-EM survey results gave conductors believed to be obtained from conductive overburden, therefore not significant to our programme.
- 3) Proton precession magnetometer survey was used to delineate the location of ultramafic bodies which show up as magnetometer high responses. The margins of these

magnetometer highs are believed to be altered by carbonatization or silicification of the ultramafic and may contain gold mineralization.

4) Drilling on the Utopia claim was done along the margins of the magnetometer highs. Quartz stockworks found in the carbonatized ultramafic in holes 3, 5, and 6 have associated pyrite, galena and chromite mineralization and good potential for gold and silver mineralization similar to that found on neighbouring properties.

Respectfully submitted,

L. Dandy, B.Sc.

Mark Management Ltd.

Some mafics altered to chlorite, some plagioclase altered to clay. Calcite on fractures and matrix slightly calcareous in places, weathers orange/brown on fractures. From 89' to 91', soft, crumbly and clayey with minor pyrite.</p> <p>Light blue/grey, brecciated, vuggy, carbonatized, silicified sub-volcanic and ultramafic - with depth ultramafic (carbonatized) fragments become more common than volcanic. Fragments cemented by very fine grained carbonate and chalcedony. Crosscutting veinlets of quartz, carbonate and quartz/carbonate.</p> <p>Blue/grey, fine to coarse grained, vuggy carbonatized ultramafic, mineralogy of rock is carbonate, quartz, upto 5% mariposite, minor chromite, trace pyrite - brecciated in places - quartz, chalcedony and carbonate veinlets of variable orientations, vuggy, very fine to coarse grained.</p> <p>Beige, very fine grained, brecciated carbonate and quartz (vein?) with crosscutting quartz stringers and a 2mm wide band of pyrite.</p> <p>Light blue/green, medium grained, competent carbonatized ultramafic with quartz and calcite veinlets commonly upto 1cm. Veinlets total less than 5% of rock, minor pyrite, brecciated in places. Quartz and carbonate roughly 'banded' from 143' to 144'.</p> <p>Beige, fine grained, crmbly quartz-carbonate rock - appears to be sheared quartz-carbonate vein.</p> <p>Light blue/grey, competent, medium grained, carbonatized ultramafic. Minor quartz and carbonate veinlets, minor pyrite. At 168.5', a 2cm quartz and rhodocrosite (purple carbonate) veinlet at 50°. Less than 5% mariposite, minor chromite. Sharp contact at 80° at 179.5'.</p> <p>Beige, fine grained competent, quartz-carbonate rock - probably a fine grained rock which has been carbonatized - in places (middle) of section it is medium grained and appears that it might have been a porphyritic volcanic. Quartz and carbonate veinlets upto 5mm</p> |                      |     |               |                             |                 |                        |           |            |  |  |

Semi quantitative multi element ICP analysis

Nitric-Aqua-Regis digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sr, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Ti, Ti, W and V can only be considered as semi-quantitative.

Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Ti, Ti, W and V can only be considered as semi-quantitative.

## Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Tl, Ti, W and V can only be considered as semi-quantitative.

### Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Ti, Ti, W and V can only be considered as semi-quantitative.

## Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Ti, Ti, W and V can only be considered as semi-quantitative.

Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sr, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Ti, Ti, W and V can only be considered as semi-quantitative.

### Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Ti, Ti, W and V can only be considered as semi-quantitative.

### COMMENTS :
