SUMMARY

A three person crew carried out a programme of geological mapping, soil sampling, and trenching on the Paydirt Claim Group from July 1 to August 1, 1986 and from August 22 to August 30, 1986. The objectives of the programme were fourfold 1) to better define at surface the mineralized body with drill indicated geological reserves of 185,000 tonnes of 4.11 g/t Au, 2) to test and evaluate a number of anomalous rock samples taken from other parts of the property, 3) to trench a number of untested soil sample anomalies, and 4) to explore for additional mineralization. The results of trenching peripheral to the "Main Zone" mineralization indicated the mineralized body pinches in thickness from 25 m to 5 m approximately 70 m south of the discovery outcrop. The gold content across the five metres assayed up to 0.14 g/t Au. Previous work had ascertained that the mineralization pinches out 80 m to the north of the discovery outcrop. Chip sampling at the sites of anomalous grab sample from the previous summer's work returned many anomalous Au assays but none approaching ore grade. Trenching and bedrock sample of soil sample anomalies produced five anomalous assays but none approaching potentially economic grade. No significant new mineralization was discovered.

RECOMMENDATIONS

Results from the 1986 exploration programme were disappointing. Anomalous Au values were detected in numerous rock samples, but all values were below potentially economic grade and there was a lack of continuity where multiple samples were taken across large structures. Soil sampling produced some spot anomalies between both Killer and Split #2 Creeks and in the area of the Great Plains copper showing. Trenching of soil anomalies produced anomalous rock samples but nothing approaching potentially economic grades.

Based on the disappointing results this year it is recommended that any future work be directed towards the gold showing, the anomalous samples in the area of the copper showings, and the spot soil geochemical anomalies between Split #2 Creek and Killer Creek. Considering the location of the property a considerable increase in both grade and tonnage potential of the property is required if a viable mining venture is to be considered.

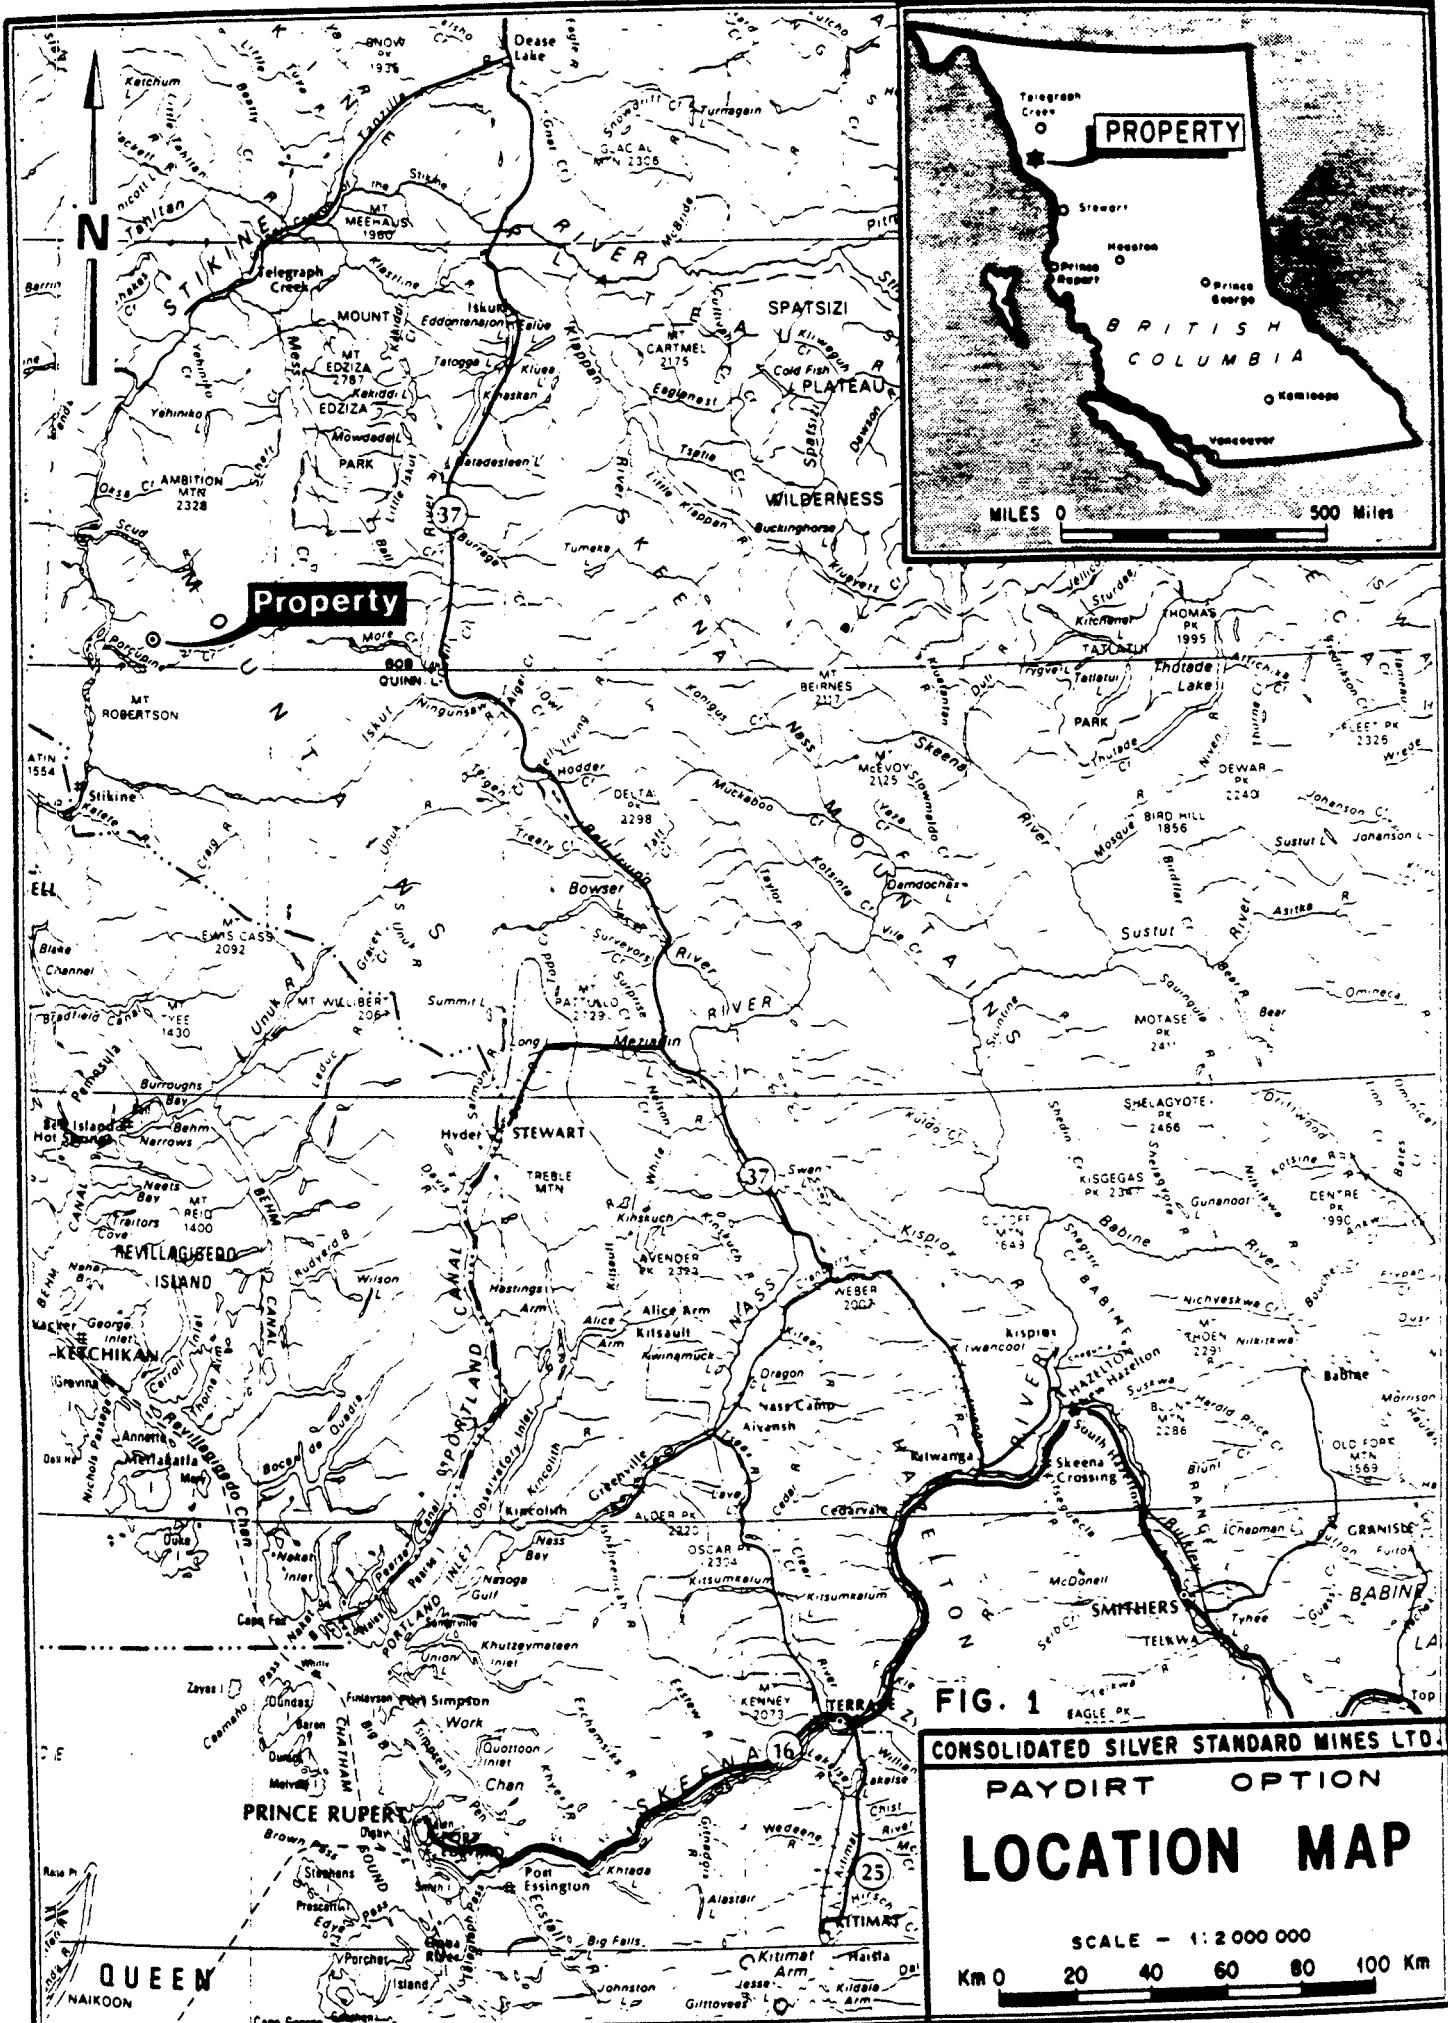

A. INTRODUCTION

This report describes a geological, soil geochemical and trenching program carried out on the Paydirt claim group between July 1, 1986 and August 30, 1986. The property is located south of Mt. Scotsimpson along the valley of Split Creek, a tributary of the Porcupine River (See Figures 1 and 2). Access to the property is via helicopter from Bob Quinn Lake, located on Highway 37, 80 km east-south-east of the claims. Alternatively, access is possible by boat up the Stikine River to its junction with the Porcupine River, then by foot 15 km east up the Porcupine River and, ultimately, up Split Creek. An old cat road follows the route from the Stikine River to Split Creek. Elevations on the property range from 500 m to 2700 m with steep relief. Below 1200 m, the property is covered by dense underbrush with large spruce trees on ridges and in the valley bottoms. The remainder of the property is covered by alpine vegetation except where outcrop and scree is present.

A.1 History

The area was staked in the 1960's to cover a weak copper porphyry system centered 500 m east of the top of Split #1 Creek. The following list outlines previous operators, claim names and activities:

1. (ca.1963) Julian Mining Co. - Ann and Su claims, I.P. surveys, geological mapping, trenching and 2200 m of diamond drilling.
2. (ca.1963) Stikine River Mines Ltd. - A.C. and Alpha claims. Geological mapping and geochemical surveys.
3. (1969) Silver Standard Mines Ltd. - Staked - no recorded work.
4. (1974) Great Plains - As claims. Geological and geochemical surveys.

5. (1981) Teck Explorations Ltd. - Paydirt Claims. Geological mapping, soil and silt geochemical sampling, magnetometer survey, trenching, and 49 m of diamond drilling.
6. (1985) Consolidated Silver Standard Mines Ltd. - Paydirt option. Geological mapping, soil sampling, diamond drilling, and trenching.

A.2 Claim Status and Economic Assessment

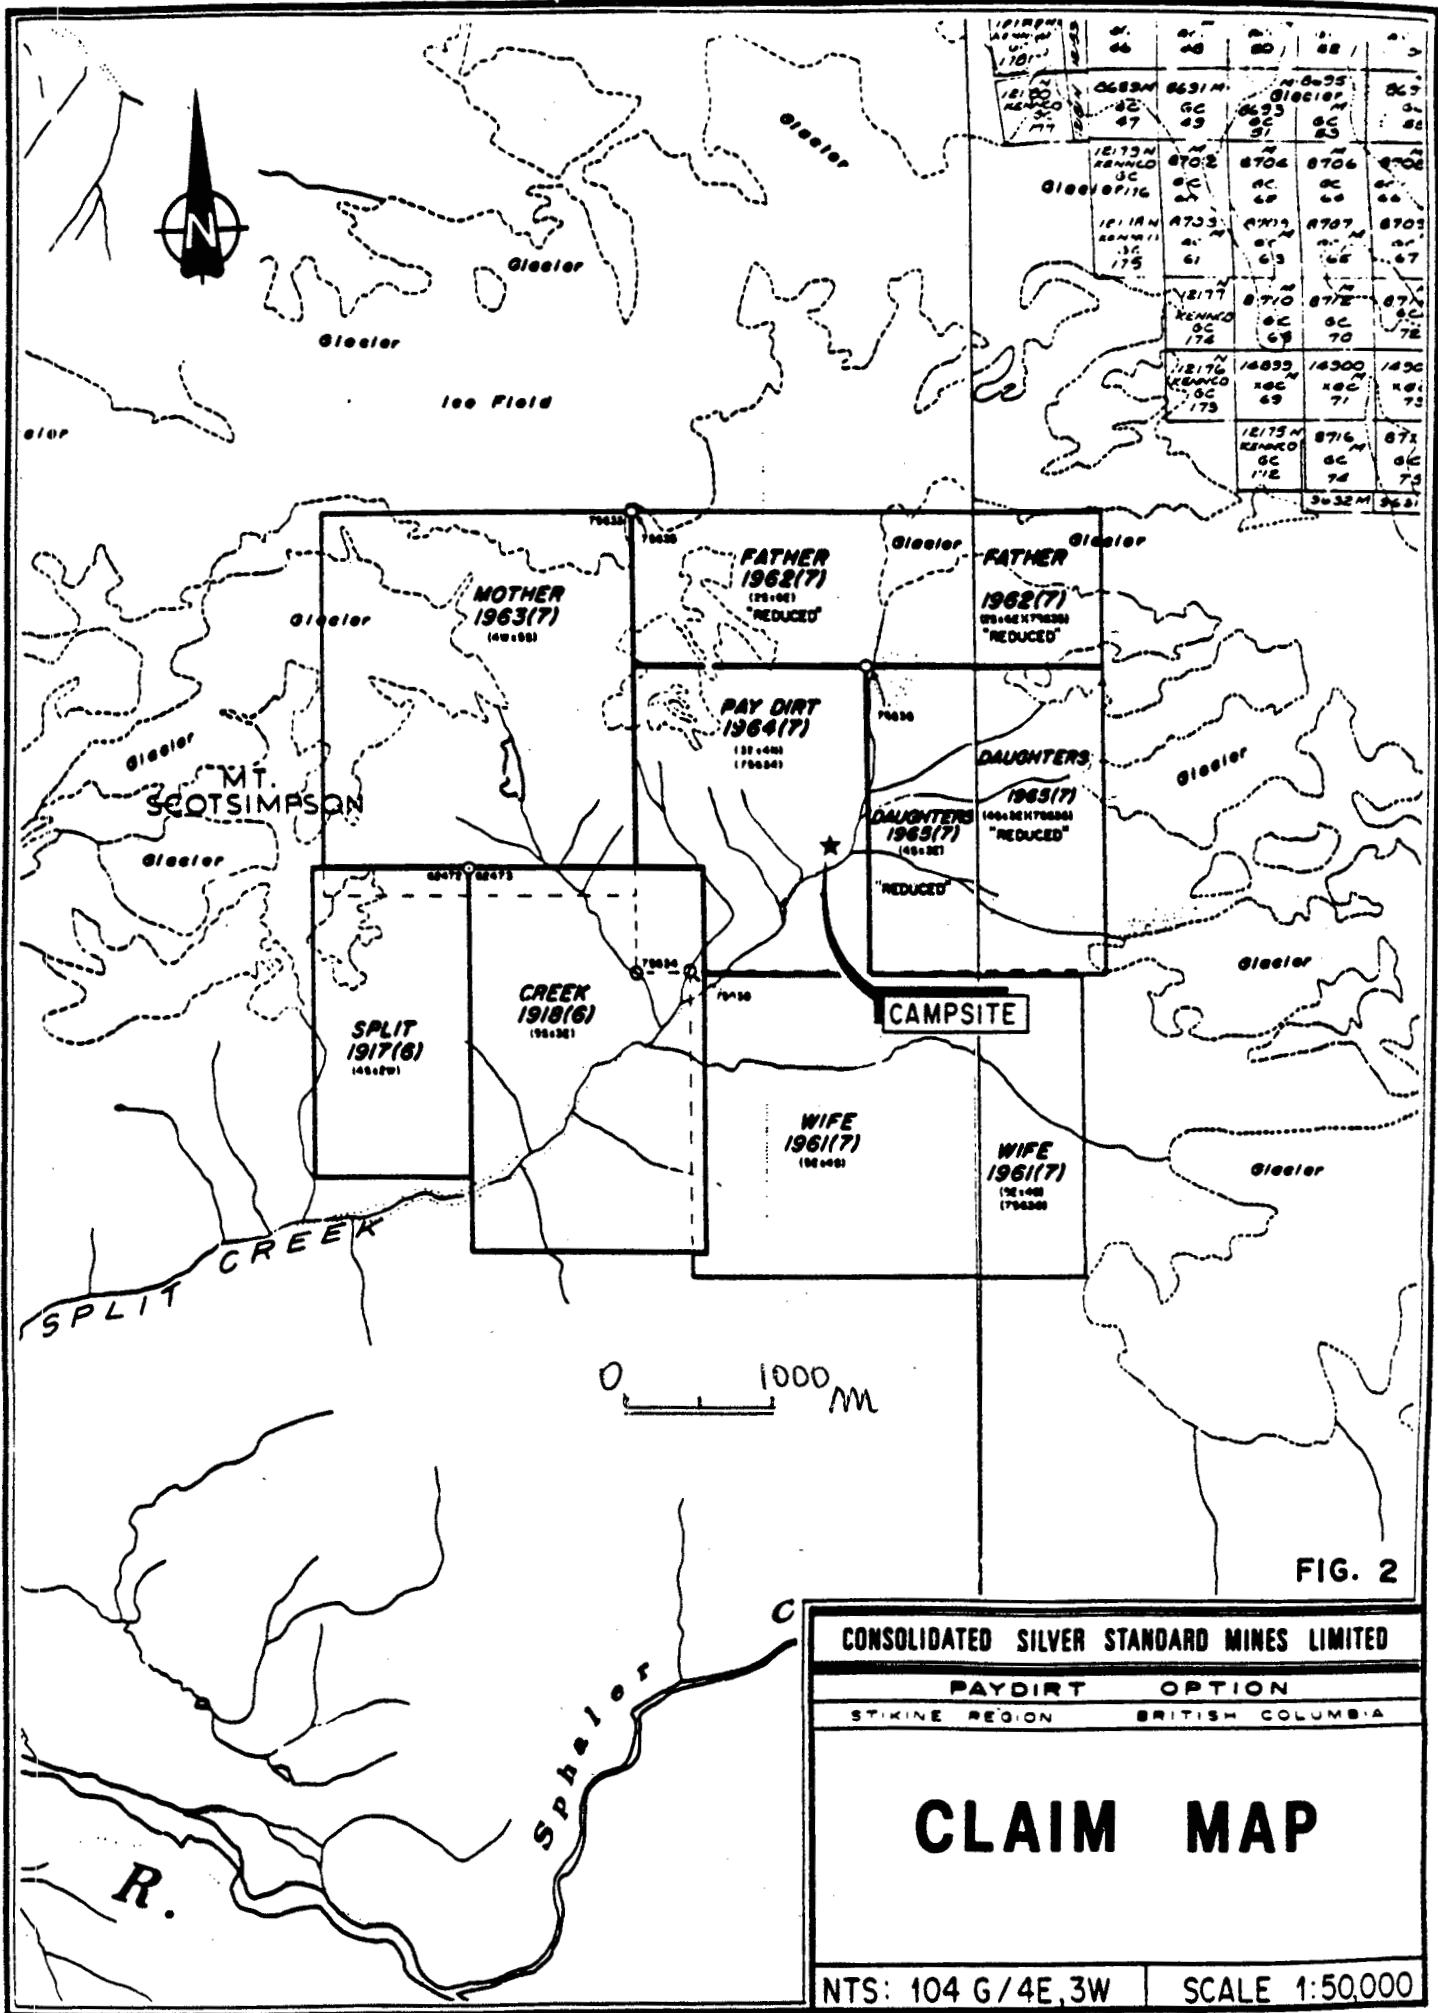

<u>Claim Name</u>	<u>Units</u>	<u>Record No.</u>	<u>Record Date</u>	<u>Expiry</u>
Split	8	1917	12 June	1991
Creek	15	1918	12 June	1991
Wife	20	1961	23 July	1997
Father	12	1962	23 July	1997
Mother	20	1963	23 July	1997
Paydirt	12	1964	23 July	1997
Daughters	12	1965	23 July	1997

The property is owned by Teck Explorations Ltd. and is under option to Consolidated Silver Standard Mines Ltd., the operator. The property has limited economic potential at this time. The drill indicated reserves of 185,000 tonnes of 4.11 g/t Au are not economic at current gold prices. No other gold mineralization of similar magnitude or continuity has yet to be found on the property.

A.3 Work Programme

This report includes detailed geological mapping at a scale of 1:5,000 of the intervening 2.25 km between Split #2 and Split #3 Creeks, describes 166.5 m of hand trenching using explosives and a Wajax pump, and discusses the results of 131 rock samples and 105 soil samples.

The work was carried out on the Paydirt, Mother and Creek claims.

B. GEOLOGY

B.1 Regional Geology

The claims lie on the eastern margin of the Coast Plutonic complex in a belt of Upper Triassic eugeosynclinal sedimentary and volcanic rocks. The volcanic-sedimentary package has been intruded by Triassic and Jurassic syenitic intrusions and Jurassic and Cretaceous diorite to granodiorite intrusions. The syenitic intrusions are related to porphyry copper mineralization, similar to that at Galore Creek 10 km to the north-east of the property. Similar mineralization probably occurs on the Paydirt property, although the nearest syenite outcrop is 1.25 km east of the copper mineralization.

Strong north-south faults are outlined by drainage patterns and may represent deep-seated structures related to the accretion of this terrain onto the North American craton.

B.2 Property Geology

The property is largely underlain by andesite pyroclastics which have been intruded by related hornblende diorite and amphibolite stocks and younger syenite and diorite to granodiorite bodies. This whole package has, in turn, been intruded by younger dykes, andesitic to lamprophyric in composition.

With the exception of the later stage dyke rocks, the rocks on the property exhibit regional propylitic alteration and wide spread pyritization. The pyrite mineralization is centered on an area between the top of Split #1 Creek and Split #2 Creek. This is the area of strongest copper mineralization where most of the work in the 1960's and 1970's was carried out. There is abundant malachite staining in most of Split #1 Creek and in the canyon in the lower part of Split #2 Creek. Strong Chalcopyrite-chalcocite mineralization can be found over widths up to 10 m. The mineralization is,

in part, structurally controlled and associated with diabase dykes. Anomalous gold values up to 1270 ppb are found associated with the copper mineralization.

The main area of gold mineralization is located on Discovery Creek, 2 km northeast of the centre of the copper mineralization, at an elevation of 1000 m and is a zone of silica-pyrite alteration in andesite pyroclastics associated with a N-S striking structure. Gold occurs in the more intensely silicified portion of this alteration zone. A more detailed description of this zone, along with 1985 drilling results can be found in "A Geological, Soil Geochemical, Trenching, and Diamond Drilling Programme on the Paydirt Claim Group," M. Holtby (1985).

Work in 1986 was concentrated on defining, by detailed geological mapping and chip sampling, a number of highly silicified, pyrite rich, and/or sericitized zones that extend from the toe of the glacier on Split #2 Creek (elevation 1000 m) to Split #3 Creek (elevation 1000-1300 m). Eight assays from 1985 grab samples in these zones ranged from .6 g/t Au to 9.3 g/t Au. On examination, the zones appear to be one continuous zone offset by two sets of faults striking 0° and 135° (See Figure 3). This zone was sampled in four locations with 40 continuous two to four metre chip samples. Most samples returned anomalous gold values up to 1.37 g/t Au but did not approach potentially economic grades. Samples were taken from surface material, where strongly silicified, or from 20 cm deep trenches in strongly sericitized areas. It is a possibility that low assay values for samples may be due to leaching. This possibility is unlikely for samples from the highly silicified, impermeable sections.

Limited mapping and sampling was carried out in other areas of the property; notably the copper showing at the south end of the canyon on Split #2 Creek (elevation 650 m) and the centre of the cat workings on the main copper showing. The showing on Split #2 Creek

canyon returned a value of 6.2 g/t from a grab sample taken in 1985. Twelve 2 metre chip samples were taken in this area. All returned anomalous gold values, but the highest was 1330 ppb Au. Nine 2 metre chip samples were taken from bedrock underlying high soil samples in the area of the cat trenches and from Split #1 Creek where 1985 grab samples returned anomalous gold values. Results of these samples were anomalous in gold, ranging up to 190 ppb, but none approached potentially economic grades. Fifty-three 1 to 2 metre chip samples were taken from trenches excavated at the sites of anomalous soil geochemical samples taken in 1985 in the area of the "Main Zone". Four of these samples were anomalous ranging up to .96 g/t Au.

Locations of all rock chip samples are on Figures 3 and 4.

C. GEOCHEMISTRY

C.1 Orientation Survey

Two pits were dug, one over an area with high gold geochemical values in soil and one in an area with background gold values in soil. Samples were taken of the "A", "B", and "C" soil horizons and of the bedrock. The soil samples were split into a +80 mesh fraction and a -80 mesh fraction. These fractions were then analyzed for Cu, Zn, Ag, As, Sb, Hg, Te, Ba, using wet extraction followed by atomic absorption, Au using fire assay with atomic absorption finish, and for 30 elements by I.C.P.

Gold values were highest in the "C" horizon -80 mesh fraction and showed a strong correlation to Cu, As, Te, and Fe and weaker correlation to Sb and Pb. Results are included in Appendix B.

C.2 Soil Sampling

Three reconnaissance soil lines were run, two from Killer Creek west on the 800 m and 900 m elevation contours to Split #2 Creek and one

across the centre of the copper prophyry system largely on the 1050 elevation contour but following a cat trench. One hundred and five samples were taken from the "B" soil horizon at 25 m intervals and were run for gold by fire assay with atomic absorption finish. The samples taken over the copper porphyry mineralization were also analyzed for copper using wet extraction followed by atomic absorption.

Four spot highs between 200 ppb Au and 1520 ppb Au were encountered on the two lines running between Killer and Split #2 Creeks over a high background of 100 ppb Au. The four highest results could be the expression of mineralization similar to the "Main Zone", although the assays are not as high as soil samples taken over the "Main Zone" and there are no adjacent supporting anomalous assays. In follow-up work trenches to bedrock should be located and sampled of these four anomalous samples in particular at the location sample 86 PD-04 which ran 1520 ppb Au. This sample is located 100 m west of Killer Creek on the 900 m elevation contour.

Two anomalous samples of 250 ppb Au and 1030 ppb Au were encountered on the soil line run across the copper porphyry system. Background values are 125 ppb Au. Overburden cover is very shallow in this area ranging from 0.5 m to 1 m in depth. Trenching of similar anomalous values from previous soil sampling surveys returned high background Au values in rock, up to 190 ppb Au and averaging 85 ppb Au. Gold values seem to be concentrated in the soil reflecting an overall enhanced gold background as opposed to economic concentrations in the rock.

C.3 Stream Sediment Sampling

Eight pan concentrate samples were taken from the drainages flowing into the headwaters of Split #2 Creek. Two of these were highly anomalous in gold, 1200 ppb Au and 8600 ppb Au. Four chip samples were taken of orange weathering, silicified, pyritized material from

the only outcrop above the site of the 8600 ppb sample (19578). The outcrop is located approximately 50 m above the sample site (See Figure 3). Assays were disappointing ranging from 15 ppb Au to 75 ppb Au. This anomaly has not been satisfactorily explained, but could be the result of glacially transported material.

Soil and pan concentrate sample results are included in Appendix B.

D. TRENCHING

A total of 166.5 m of trenches were hand excavated using a Wajax 26B pump, pionjaar drill, and explosives. Eleven trenches were completed to bedrock located at anomalous soil samples obtained in previous work. Seven of these trenches were in the area of the "Main Zone", three others, previously discussed under "Soil Sampling" were on the copper porphyry system, and one trench, previously mentioned under "Property Geology" was on two 1985 samples that ran 2.17 g/t Au and 8.37 g/t Au.

Chip samples from bedrock exposed in the seven trenches in the area of the "Main Zone" (see Figure 4), returned background values with the exceptions of trench #11 and trench #17. Trench #11 was located at the intersection of Line 9+70N and the trail from base camp to the "Main Zone". This is the location of Anomaly F from "A Geological, Soil Geochemical, Trenching, and Diamond Drilling Programme on the Paydirt Claim Group" Holtby, M. (1985). Values in this trench were associated with minor chalcopyrite mineralization and ranged from 0.14 g/t Au to 0.96 g/t Au. Trench #17 was located on line 9+70N, 90 m west of Discovery Creek on Anomaly C in the above mentioned report. Two anomalous values of .11 g/t Au and .235 g/t Au were returned from eight one metre samples taken.

None of the assay values for rock samples taken from the trenches approach potentially economic grades. All soil anomalies identified in the 1985 work were trenched either to bedrock or transported material immediately overlying bedrock.

STATEMENT OF COSTS

Personnel

J. Bacon	1/1/86 - 4/8/86, 22-30/8/86 44 days at \$95/day = \$4,180 + benefits	\$4,807.00
P. Daubeny	26/6/86, 1/7/86 - 4/8/86, 22-30/86 45 days at \$85/day = \$3,825 + 15% benefits	4,398.75
D. Dunn	20,23,26/6/86, 1/7/86 - 4/8/86, 22-30/86, 21,24-28/11/86 53 days at \$165/day = \$8,745 + 15% benefits	10,056.75
J. Havlik (Research)	9 hours at \$7.57/hr. = \$68.13 + 15% benefits	78.35
A. Potter	3,26/7/86, 3-4/8/86 4 days at \$125/day = \$500 + 15% benefits	575.00
R. Quartermain (Administration)	62.5 hours at \$32.04/hr. = \$2,002.50 + 15% benefits	2,302.88

STATEMENT OF QUALIFICATIONS

I, David Saint Clair Dunn, of the Municipality of West Vancouver, in the Province of British Columbia, hereby certify as follows:

1. I am a Geologist residing at 2348 Palmerston Avenue, West Vancouver, B.C., V7V 2W1.
2. I am a Fellow of the Geological Association of Canada.
3. I am a graduate of the University of British Columbia with a B.Sc.-Geology (1980).
4. I have practiced my profession as a Geologist since graduation.
5. I have worked in the mineral exploration industry for eight seasons previous to graduation.
6. Geological mapping, rock sampling and geochemical surveys were carried out by experienced exploration personnel under my supervision.

David Saint Clair Dunn, F.G.A.C.

Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Ti, Ti, W and Y can only be considered as semi-quantitative.
