1. INTRODUCTION

Between October 1 and December 30, 1986, Noranda Exploration Company, Limited (No Personal Liability) of 1050 Davie Street, Vancouver, B.C. contracted Amex Exploration Services Ltd. of Kamloops B.C. to conduct a detailed soil geochemical survey on the Hope Property.

The target was a sedimentary hosted and/or skarn related massive sulphide (Zn,Pb,Ag).

Four hundred and ten soil samples were taken on 10 kms of grid lines and geochemically analyzed for ppm Ag, Zn, Pb, Cu and ppb Au at Noranda Exploration Company, Limited's laboratory at 1050 Davie Street, Vancouver, B.C. (See Appendix B for laboratory analytical methods.)

2. LOCATION AND ACCESS

The Hope property is located some 6 kilometres S.E. of Slocan, B.C. at longitude 117°25'W and latitude 49°44'N on N.T.S. map sheet 82F/11, within the Slocan Mining Division.

Access is good via logging roads from Highway 6 along Lemon Ck. road and then Chapleau Ck. road which passes the eastern boundary of the Hope 3 and 4 claims.

3. TOPOGRAPHY AND VEGETATION

The Hope property encompassing Cameronian Creek is generally steep in terrain with a maximum relief of 2700 feet and a maximum elevation of 5900 feet.

Slopes are generally tree covered with a thin to moderate layer of soil and/or talus.

4. PROPERTY INFORMATION

Table 1 is a list of 10 claims (47 units) which are owned in part by Chapleau Resources Ltd. of Cranbrook, B.C. and Mrs. Kennedy of South Slocan, B.C.

The property is currently under option to Noranda Exploration Company, Limited (No Personal Liability).

5. PROPERTY HISTORY

Majority of work conducted on the Hope Property prior to 1985 was centered on the Hope 2 claim.

The following summarized history (prior to 1960) is taken from Little 1960.

" The property was not productive during the period of early development, from 1898 to 1901. In 1926 it was acquired by Piedmont Mines, Limited, who extended the underground workings in an effort to delineate the deposits and they installed an aerial tramway and mill. In 1928 and the early part of 1929 nearly 400 tons of ore was mined and treated before the mine and mill were shut down. In 1948 and 1951, 25 and 12 tons of ore were shipped by lessees.

In the period 1928 to 1951 inclusive, 525 tons of ore was produced, yielding 156,477 pounds zinc, 50,216 pounds lead, and 1,984 ounces silver. The property was examined in July 1950, by A.B. Irwin of the Geological Survey. "

According to Allen (1986) the property was examined and sampled by E. Caldwell in 1949 for Consolidated Mining and Smelting Co. (C.M.S.C.). Reserve calculation of the Glory Hole by C.M.S.C. suggested a potential of about 143,000 tons grading 7.7 ounces per ton silver, 7.9% lead and 17.4% zinc (Allen 1986).

During 1985 Chapleau Resources Ltd. conducted a preliminary contour soil geochemical and magnetometer survey along with a geological mapping programme contracted to Donald G. Allen of Vancouver, B.C.

6. LOCAL GEOLOGY

According to Allen, 1986, the Hope Property is underlain in part by a roof pendant of Triassic, Slocan Group meta-sediments lying within a Nelson Granodioritic Batholith Complex.

Metasediments consist largely of argillite, quartzite, macaceous quartzite and minor carbonate horizons. Beds generally strike NW-SE with shallow dips to the SW.

Most significant mineralization on the property is a massive sulphide body of the old workings, referred to as the Glory Hole (see Diagram 2). Mineralization, consisting largely of sphalerite, pyrite, pyrrhotite, and minor galena, appears to be locally skarned (garnet/epidote) by the proximal batholith complex.

Also of interest is an approximately one foot wide bed of massive pyrrhotite, pyrite, sphalerite and galena which is stratigraphically conformable within quartzitic horizons. (See Zone 1, Diagram 2.)

This latter zone of bedded massive sulphide indicates the potential for further mineralization on the property other than that found in the Glory Hole.

7. SOIL GEOCHEMICAL SURVEY

7.1 Survey Control and Sampling Method

Grid establishment and soil sampling were contracted to Amex Exploration Services by Noranda Exploration Company, Limited (No Personal Liability).

The grid consists of 10 one kilometre wing lines spaced at 100 metre intervals along a 900 metre baseline which strikes Az 290°.

Each wing line was compassed, slashed and straight chained with flagged stations every 25 metres.

The 410 soils were taken at numbered flagged stations every 25 metres along wing lines. Each was obtained by digging holes with a maddock or shovel to a depth of 15 to 30 cm. where the visible B horizon, whenever possible, was exposed and sampled. Samples were then placed in a "Hi Wet Strength Kraft 3 1/2" by 6 1/8" Open End" envelopes with grid co-ordinates marked on the envelope with an indelible felt pen.

7.2 Presentation and Discussion of Results

Soil analyses are presented by tabular format in Appendix A as well as being contoured on Drawings 2 through 6. Contour intervals were obtained by visual inspection of the data.

Zn - Zinc values range from 90 ppm to 12000 ppm and are contoured at 1000, 2000, 4000 and 8000 ppm on Drawing 2.

One large, somewhat circular, anomalous zone centered on the north-eastern portion of the grid was delineated. This zone is bound to the south and west by Cameronian Creek which may represent fault structures.

The zinc anomaly contains both grid north-south and east-west trends. The grid east-west component is believed to depict bedded type mineralization. Similar to that of showing 2. While the grid north-south component may represent either down slope movement and/or faulted blocks of stratigraphy. With faults being similar in attitude to Cameronian Creek's western tributary. Which strikes grid north-south and bounds the zinc anomaly in the west.

Also of interest is the narrow grid east-west striking zinc anomaly which is proximal to showing 1 (see Diagram 2).

Pb - Lead analyses range from 8 ppm to 7700 ppm with contours of 100, 200, 800 and 3200 ppm on Drawing 3.

Lead contours depict a large arcuate shaped anomalous zone which is coincident with a similarly shaped zinc anomaly delineated by a 4000 ppm Zn contour.

Ag - Silver values range from 0.2 to 61.0 ppm with contours at 2.0, 4.0, 8.0, 16.0 and 32.0 ppm on Drawing 4.

The silver analyses form a 300 m long somewhat oval shaped anomaly. Which is coincident with the strongest zinc/lead soil analyses. This zone is centered on the Glory Hole area. Contamination may be a factor, but some of the anomalous soils were taken along and up slope from the old workings.

Cu - Copper analyses ranging between 8 and 600 ppm are contoured at 100, 200 and 400 ppm on Drawing 5.

Two anomalous zones were delineated. One of these is associated with the ZN/Pb/Ag anomaly in the Glory Hole area. The other is a narrow 300 metre long zone located near stations 10550N on lines 10400E, 10500E, 10600E and 10700E. This zone is in part coincident with a long narrow zinc anomaly which may be related to showing 1 (see Drawing 2).

Au - Gold analyses range from 10 ppb to 1100 ppb with contour intervals of 20, 50 and 100 ppb on Drawing 6.

Numerous sporadic one station anomalies occur throughout the grid and appear to be of little significance.

Two weak 2 station anomalies are located between 10500N and 10600 N on lines 10300E/10400E and 10600E/10700E. These are in part associated with the long narrow coincident Zn/Cu anomaly of showing 1 and should be further investigated.

Also of possible interest is a 200 metre long weak Au soil anomaly located in the north-east section of the grid. This anomaly at station 10800E/10725N has a coincident Zn, Pb, Ag and Cu response.

8. SUMMARY AND RECOMMENDATIONS

During the period October 1 to December 30, 1987 a soil geochemical survey consisting of 410 soil samples was conducted by Amex Exploration Services for Noranda Exploration Company, Limited.

One large area anomalous in zinc was delineated, within, which were numerous individual or multi-element Pb, Ag, Cu, Au anomalous zones.

Two distinct trends did appear. One was grid east-west (parallel to bedding) with the other being grid north-south. Both appear to be associated with existing massive sulphide mineralization.

Cameronian Creek and its tributaries may represent fault structures as they form an abrupt limit to the zinc soil expression.

Detailed geological mapping along with magnetometer, E.M. and/or I.P. geophysical surveys are recommended for the next phase of work on the Hope property grid.

LABORATORY ANALYTICAL METHODS

NORANDA

ANALYTICAL METHOD DESCRIPTIONS FOR GEOCHEMICAL ASSESSMENT REPORTS

Revised: 01/86

The methods listed are presently applied to analyse geological materials by the Noranda Geochemical Laboratory at Vancouver. (March, 1984)

Preparation of Samples

Sediments and soils are dried at approximately 80°C and sieved with a 80 mesh nylon screen. The -80 mesh (0.18 mm) fraction is used for analysis.

Rock specimens are pulverized to -120 mesh (0.13 mm). Heavy mineral fractions (panned samples) are analysed in its entirety, when it is to be determined for gold without further sample preparation. See addendum.

Analysis of Samples.

Decomposition of a 0.200 g sample is done with concentrated perchloric and nitric acid (3:1), digested for 5 hours at reflux temperature. Pulps of rock or core are weighed out at 0.2 g or less depending on the matrix of the rock, and twice as much acid is used for decomposition than that is used for silt or soil.

The concentrations of Ag, Cd, Co, Cu, Fe, Mn, Mo, Ni, Pb, V and Zn (all the group A elements of the fee schedule) can be determined directly from the digest (dissolution) with an atomic absorption spectrometer (AA). A Varian-Techtron Model AA-5 or Model AA-475 is used to measure elemental concentrations.

Elements Requiring Specific Decomposition Method

Antimony - Sb: 0.2 g sample is attacked with 3.3 mL of 6X tartaric acid, 1.5 mL conc. hydrochloric acid and 0.5 mL of conc. nitric acid, then heated in a water bath for 3 hours at 95°C. Sb is determined directly from the acid solution with an AA-475 equipped with electrodeless discharge lamp (EDL).

Arsenic - As: 0.2 - 0.4 g sample is digested with 1.5 mL of 70% perchloric acid and 0.5 mL of conc. nitric acid. A Varian AA-475 equipped with an As-EDL measures the arsenic concentration of the digest.

Barium - Ba: 0.1 g sample is decomposed with conc. perchloric, nitric and hydrofluoric acid. Atomic absorption using a nitrous oxide-acetylene flame determines Ba from the aqueous solution.

Bismuth - Bi: 0.2 g - 0.3 g is digested with 2.0 ml of perchloric 70% and 1.0 ml of conc. nitric acid. Bismuth is determined directly from the digest into the flame of the AA instrument c/w EDL.

Gold - Au: 10.0 g sample (Pan-concentrates see below) is digested with aqua regia (1 part nitric and 3 parts hydrochloric acid). Gold is extracted with Methyl iso-Butyl ketone (MIBK) from the aqueous solution. Gold is determined from the MIBK solution with flame AA.

Magnesium - Mg: 0.05 - 0.10 g sample is digested with 4 ml perchloric/nitric acid (3:1). An aliquot is taken to reduce the concentration to within the range of atomic absorption. The AA-475 with a nitrous oxide flame determine Mg from the aqueous solution.

Tungsten - W: 1.0 g sample sintered with a carbonate flux and thereafter leached with water. The leachate is treated with potassium thiocyanate. The yellow tungsten thiocyanate is extracted into tri-n-butyl phosphate. This permits colourimetric comparison with standards to measure tungsten concentration.

Uranium - U: An aliquot, taken from a perchloric-nitric (3:1) decomposition, usually from the multi-element digestion, is diluted with water and a phosphate buffer. This solution is exposed to laser light, and the luminescence of the uranyl ion is quantitatively measured on the UA-3 (Scintrex).

LOWEST VALUES REPORTED IN PPM

Ag - 0.2	Mn - 20	Zn - 1	Au - 0.01 (10PPB)
Cd - 0.2	Mo - 1	Sb - 1	W - 2
Co - 1	Ni - 1	As - 1	U - 0.1
Cu - 1	Pb - 1	Ba - 10	
Fe - 100	V - 10	Bi - 1

APPENDIX D
STATEMENT OF QUALIFICATIONS

S T A T E M E N T O F Q U A L I F I C A T I O N S

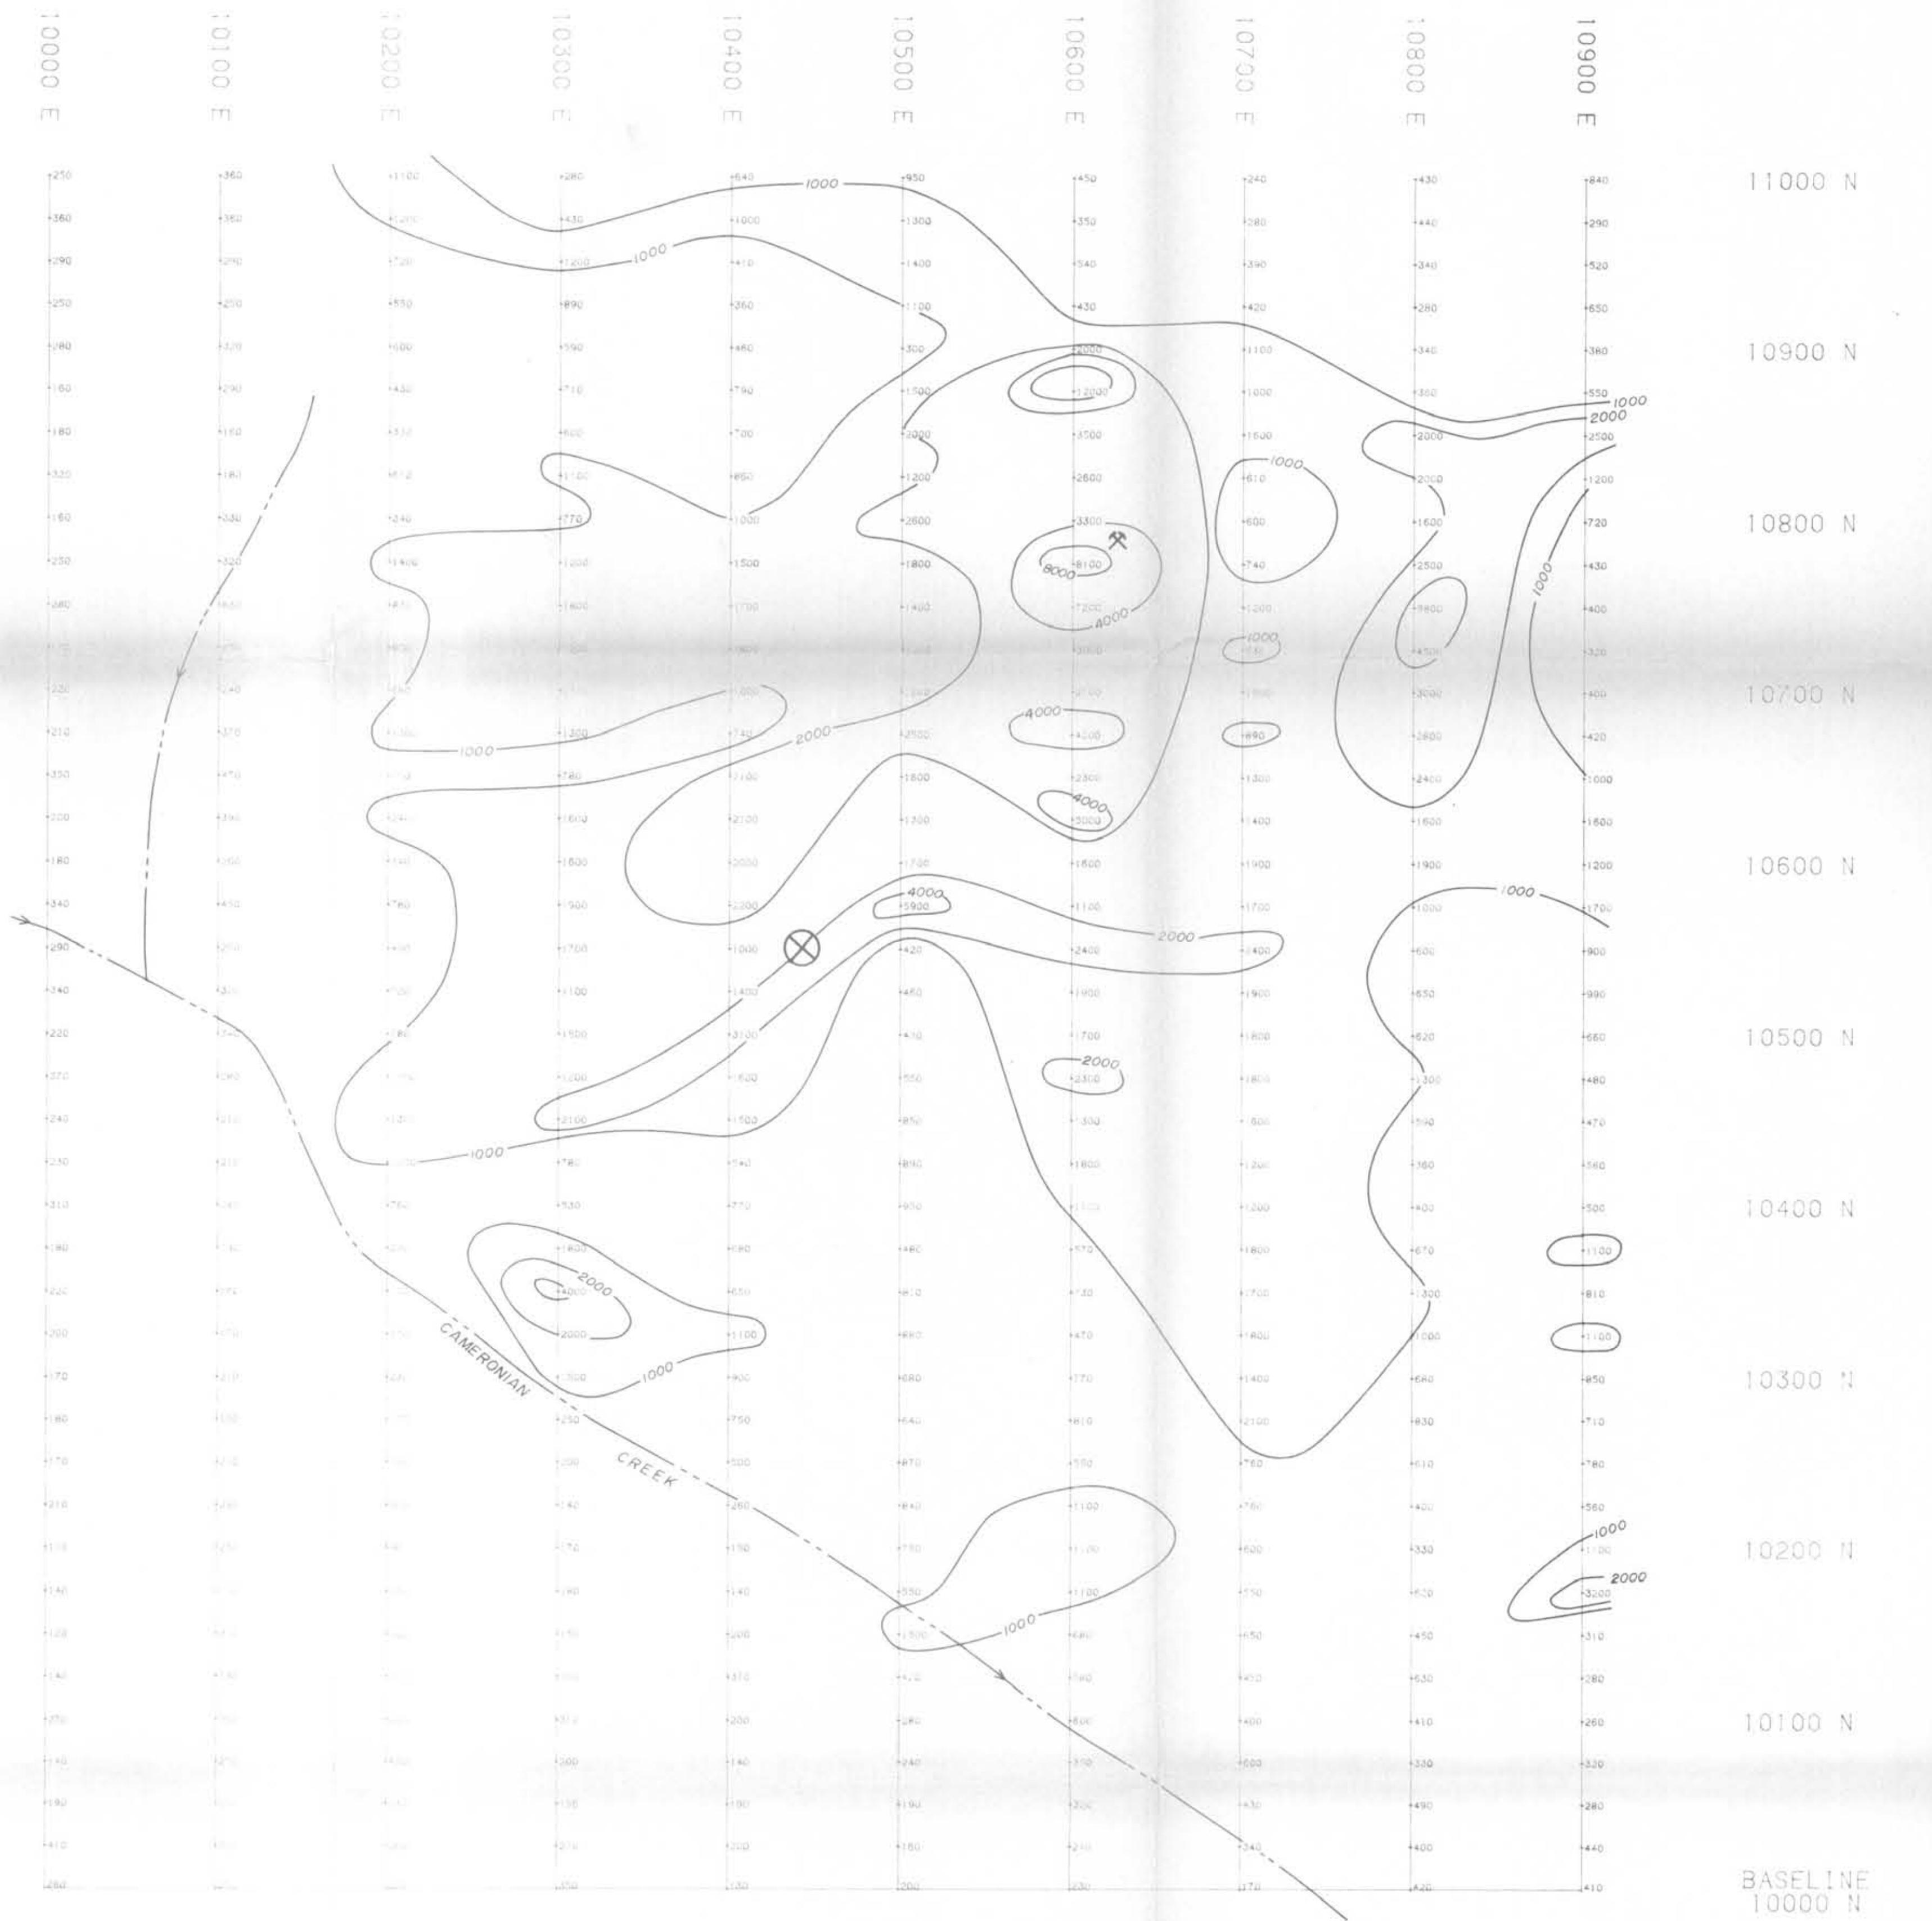

I, John G. Keating of the City of Vancouver, Province of British Columbia,
do hereby certify that:

- I am a resident of British Columbia, residing at 335 East 47th Avenue,
Vancouver, B.C.
- I am a graduate of Concordia University, Montreal, with a Bachelor of
Science Degree in Geology.
- I am a member in good standing with the Canadian Institute of Mining
and Metallurgy.
- I have been a temporary employee with Noranda Exploration Company, Limited
(No Personal Liability) since May, 1979 and a permanent employee since
March, 1983.

John G. Keating
