## SUMMARY:

This report is written at the request of D. F. B. Whiting, President of Rosalie Resources Ltd. It describes VLF-EM and ground magnetic surveys carried out on a newly cut grid laid in the vicinity of the Jack Rabbit showing. Overall supervision of the project was carried out by our Company. The VLF-EM survey was done by Interpretex Resources Ltd. personell, who also wrote the geophysical report included as Appendix No. 3.

Little is known of the Jack Rabbit showing. B.C. Government reports describe sampling at the time of discovery which returned 0.30 oz/ton gold, 2.6 oz/ton silver and 2.5% copper across 4.0 ft and a fifteen inch wide higher grade section. Recent sampling confirm the presence of mineralization but not its high grade nature.

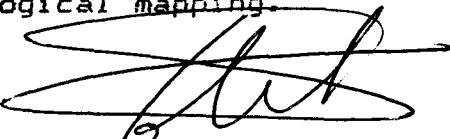

The work described in this report was carried out between October 5th and December 31, 1986 with the able assistance of those named in Appendix No. 2.

The ground magnetometer survey results are presented in Figures No. 3, 3.1 and 3.2 while the VLF-EM survey results are presented in Figures No. 5, 5.1 and 5.2.

Figure No. 4 is a Compilation Map of all data available to the writer. While the bulk of the geophysical interpretative data included is credited to Interpretex Resources Ltd. personell, the conclusions and recommendations derived from them are the responsibility of the writer.

The Compilation Map shows that the Jack Rabbit showing is located along the eastern edge of a zone of high magnetic susceptibility of unknown origin. This zone is adjacent to a narrow magnetic susceptibility low which correlates with the Quartz Feldspar monzonite dyke seen on outcrop. A weak VLF-EM anomaly runs along the eastern edge of the dyke and may reflect a fault also seen on outcrop.

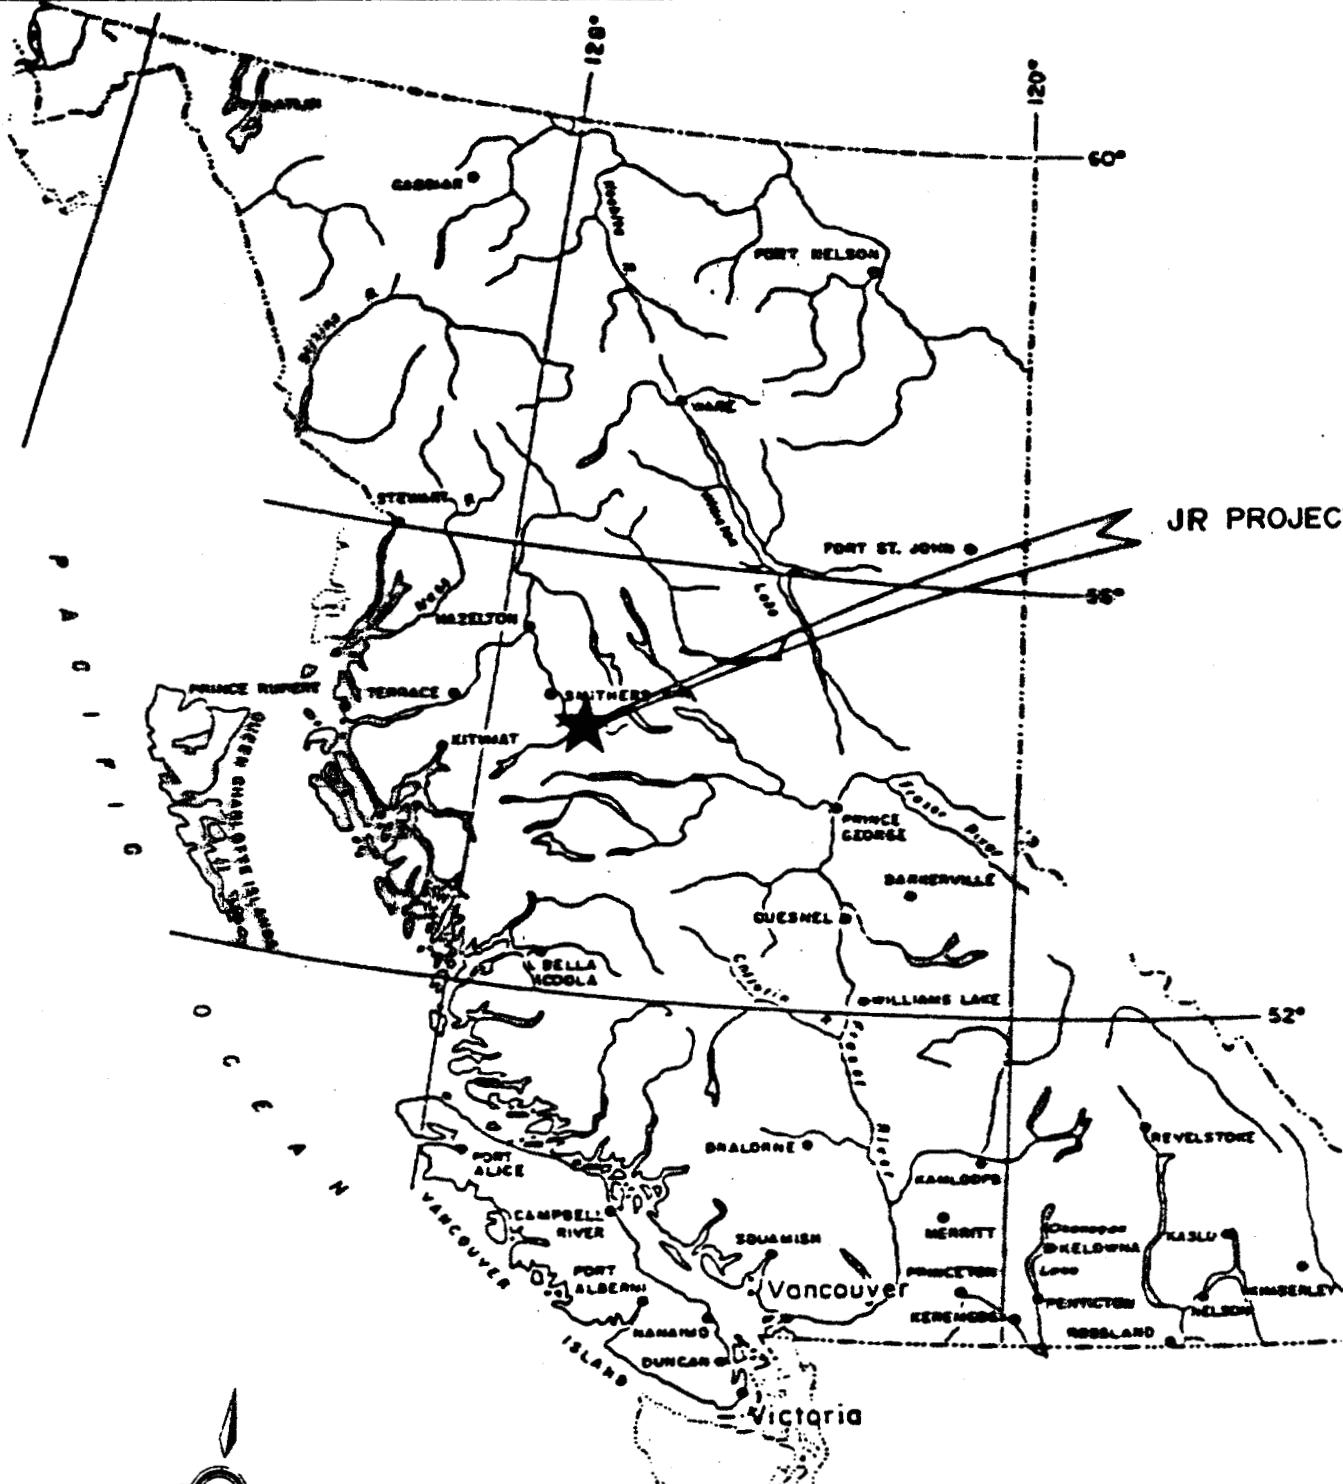

A number of other VLF-EM and magnetic anomalies are described. All are at an early stage of definition and require more work prior to physical testing. It is recommended that this work include soil sampling and geological mapping.

February 15, 1987

### INTRODUCTION:

The work subject of this report was carried out at the request of Dr. Francis B. Whiting, president of ROSALIE RESOURCES LTD. ("Rosalie"). It was supervised by the writer with the assistance of those named in Appendix No. 2.

### PROPERTY DESCRIPTION:

Table No. 1 summarizes the pertinent title data related to this property.

TABLE No. 1: CLAIM STATUS

TOTAL: 48 UNITS. (NET: 36 units)

(1): ORL: Orion Resources Ltd. FBW: F.B. Whiting  
MDG: M.D. Gumpel

Rosalie has entered into option agreements with the several owners of record.

### LOCATIONS:

The claims protect the old Jack Rabbit showing, which is located at the headwaters of a eastern tributary to Johnny David creek at an elevation of 915.0m., about 6.0 km. north northeast of the village of Perow, which is on the Yellowhead highway (No. 16), half way between Prince George and Prince Rupert. Perow is approximately 640.0 km. northwest of Vancouver and 240.0 km. west

of Prince George. See Figure No. 1.

The British Columbia Government's MINFILE carries this showing as its number 93L019, is No. 93L9-Au1 in the National Mineral Inventory and is located at UTM coordinates Z:262, N:XL6049900, E:XL0668000 by them.

#### ACCESS:

The property is accessed by helicopter or, from Ferow, Highway 16 is followed 4.0 km. easterly, where a rough 4x4 road goes up Johnny David creek a distance of 5.6 km. in a northerly direction, to the collapsed portal.

#### PHYSIOGRAPHY AND CLIMATE:

The area north of Ferow lies within the Nechako Plateau and is, characteristically, an area of gently rolling topography with occasional peaks reaching elevations to 1,500.0m. The topography of the claims is flat, ranging in elevation between 875.0m. and 1,100.0m.

At the claims area, the plateau is incised by Byman, Johnny David and Robert Hatch creeks, which drain southerly into the westerly flowing Bulkley River.

Warm summers and cold winters characterize the weather of the Interior Plateau of British Columbia. Precipitation is moderate. Occassional very low temperatures are interspersed with warmer periods in winter. Moderate depths of snow cover the region from November through April.

#### PREVIOUS EXPLORATION:

The showings were discovered in 1928 by Mathew Sam and Johnny Davies, who then optioned the claims to F.H. Taylor for a brief period. The discoverers tested the showing with trenches and a 27 foot long adit. The 1928 B.C. Min. of Mines report (p. C177) describes the showing as follows:

"... The mineralization is chalcopyrite with a little copper stain. Of these, [the several parallel mineralized fractures] only one seems to be of

importance. This is exposed by open cut and is seen to be 4 feet in width. A sample across 4 feet assayed: Gold; 0.30 oz. to the ton; silver, 2.6 oz. to the ton; copper, 2.5%. A sample across the 15-inch seam of chalcopyrite assayed: Gold: 1.24 oz. to the ton; silver, 5 oz. to the ton; copper, 9.4 per cent. An adit-tunnel was run about 20 feet below this point and at the time of inspection had advanced a distance of 27 feet. It disclosed nothing of importance, but appearances suggested that it might be in the hangingwall."

Other open cuts are reported upstream from the showing for a distance of about 35 feet.

The property lay idle until 1966, when it was staked and later optioned to Silver Cup Mines during the rush for typical Babine Lake area porphyry copper deposits. Silver Cup completed about a thousand feet of bulldozer trenching.

The area was later staked as the 71 unit Susan, Helen, Dana and Dianne claims by J. H. Montgomery (1970) and as the 34 unit SAW group by Phelps Dodge in 1973. Work during this time included soil geochemistry, ground magnetometer and Induced Polarization over widely spaced lines designed to test the area's porphyry copper potential.

The area was staked in 1983 as a result of the renewed interest in gold of recent years.

#### WORK DONE IN 1986:

The work was carried out between October 5th and December 31, 1986. It consisted of the following:

1. 2.0 line kilometers of baseline and 11.0 line kilometers of grid line spaced every 100.0m. with stations every 10.0 meters.
2. Magnetometer and VLF-EM surveys over the cut grid.
- and 3. Relocation of claim corner posts, where found.

Access was by 206 Jet Ranger operated by Northern Mountain Helicopters out of their Houston base. The VLF-EM survey was done by Interpretex Resources Ltd. while the linecutting, magnetometer survey and overall management of the program was the

responsibility of our Company.

Interpretex Resources Ltd.'s report for the VLF-EM and ground magnetometer surveys are included as Appendix No. 3 to this report.

#### GEOLOGY:

This area of the Nechako Plateau is noted for its lack of outcrop and quaternary glacial deposits.

The area protected by the claims is shown at the northern edge of Oligocene age Endako group volcanics in contact with lower Jurassic upper Hazelton group volcanics of the Telkwa and Nilkitkwa formations. In the area of the Jack Rabbit showing, the older rocks are intruded by a quartz feldspar porphyry dyke of quartz monzonite composition which forms the eastern wall to the known vein mineralization. See Figures No. 2 and 4.

Moderate to weak epidote and weaker chlorite and pyrite are widespread alteration products observed primarily in the volcanics. Magnetite, as an alteration product associated with epidote is recognized on outcrop.

#### MINERALIZATION:

The Jack Rabbit showing is by far the more interesting target known in the area. The assays reported in the 1928 Ministry of Mines Report are 0.30 and 1.24 oz/ton gold; 2.6 and 5. oz/ton silver and 2.5 and 9.4 percent copper across 4 feet and 15 inches, respectively, on samples taken from outcrop.

Samples taken by F. B. Whiting and the writer on October 5, 1986, returned the following values:

GOLD g/tonne	SILVER g/tonne	COPPER %	REMARKS
=====			
4.9	6.5	0.22	Chip sample across 5.0 ft. above collapsed adit.
0.28	4.1	1.82	Grab of highly oxidized dump material.
0.07	<0.7	0.18	Grab of oxidized volcanics near Station 5N-0E.

GOLD g/tonne	SILVER g/tonne	COPPER %	REMARKS (cont.)
0.07	<0.7	0.07	Grab from OFF dyke 75.m. NE of adit, across creek.
0.07	<0.7	N.A.	Quartz carbonate material in creek bottom near adit.

Seraphim reports widespread weak copper mineralization in the range of 0.02% to 0.07% in samples collected from intrusive and volcanic rocks away from the vein and within an area about 60.0m long along the creek and east of the Jack Rabbit showing. His two samples taken from above the old tunnel assayed 0.27% and 0.17% copper. He reports no other assays.

#### GEOPHYSICAL SURVEYS:

The magnetic and VLF-EM data results are discussed by E.R. Rockel and T. Matich, both of Interpretex, in a report included in this report as Appendix 3. The following discussion of results is a summary of their report and a discussion of how the data gathered this season relates to geological and geophysical data found in the References.

Figure No. 4, labelled "COMPILATION AND CLAIM SURVEY MAP" shows Interpretex's geophysical interpretation to which have been added the following:

- 1. Claim posts and boundaries, where known.
- 2. Major topographic features.
- 3. The approximate location of the tunnel/adit into the Jack Rabbit showing.
- and           4. Outcrop geology, as presented by R. H. Seraphim.

#### Ground Magnetic Survey:

Figure No. 3 shows the diurnally corrected ground magnetic results on a profile format. Here, it is shown that readings were taken every ten meters on lines spaced 100.0 m. apart as well as along the baseline. The data is plotted on a contour format in Figure No. 3.1 and as a three dimensional map on Figure No. 3.2, all of which were prepared by Interpretex Resources Ltd.

The Jack Rabbit showing is located along the eastern boundary of magnetic feature "M-1". Matich and Rockel's

northwesterly fault cuts this feature in between Lines 8+00N and 9+00N. This magnetic feature coincides with the one previously described by Beaton in Assessment Report No. 4760, which he correlates to ..."a north trending elliptical [magnetic] high of 100 gammas relief ..[shown on Aeromagnetic Series Map Sheet No. 5312 covering]... over a length of approximately 1 mile."

The narrow zone of low magnetic susceptibility adjacent to zone "M-1" on Lines 5+00N and 6+00N overlies the Quartz Feldspar monzonite porphyry dyke seen east of the Jack Rabbit showing.

Distinctive high magnetic susceptibility readings found at L4+00N/2+50E and B.L./4+50N define a northeasterly trending interpreted fault that seems to cut off the M-1 magnetic anomaly, the low associated to the Quartz Feldspar monzonite porphyry Dyke and a twin peak magnetic anomaly found in L5+00N between Station 0+50W and Station 0+30E, L6+00N between Stations 1+00W and 0+25E and the baseline between the two lines.

The twin peak magnetic anomaly described above as well as the other isolated magnetic highs may be caused by an increase in the amount of magnetite near surface.

#### VLF-Electromagnetic Survey:

A number of short (400.m. or less), north to northwesterly trending VLF electromagnetic (VLF-EM) anomalies parallel the claims' geological grain. Matich and Rockel concluded that ..."good profile character seems to suggest a geological, rather than an overburden cause for the strong VLF-EM anomalies. The short wavelength, moderate to weak anomalies of general low conductance indicate near surface conductive zones which are probably narrow..."

Conductors "A", "B" and "C" are identified and described by Matich and Rockel. Conductor "D", in turn, was also identified by them but as a weak conductor. It is enhanced in this report because it follows the eastern contact of the quartz feldspar monzonite porphyry dyke as defined by Seraphim's mapping and the coincident magnetic low previously described. The weak conductors identified by Matich and Rockel at L8+00N/2+00W and L9+00N/2+40W appear to have similar but weaker conductance than shown to the southeast. Should this be indeed a continuation of Conductor "D", the displacement along the northwesterly fault that cuts it and magnetic anomaly "M-1" between Lines 7+00N and 8+00N would be minimal.

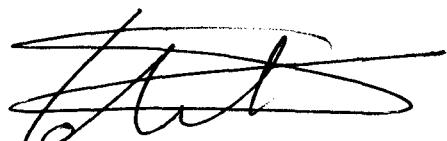

Another weak VLF-EM conductor parallels the western edge

of magnetic anomaly "M-1", its significance should be investigated.

**RECOMMENDED PROGRAM:**

The following work is recommended:

1. Soil geochemical survey over the entire grid, specially the area north of L3+00N. These soil samples should be collected every ten meters. Every other sample should be analysed at first with the exception of the showing area, where all samples should be run. Samples should be analysed for gold and silver by fire assay/ atomic absorption methods and for copper by atomic absorption methods. Multielement tracer geochemistry may be usefull once it is confirmed that the soil horizon being sampled is testing bedrock.
2. The grid area should be geologically mapped at a scale of 1:2,500.
3. Pending the results found, drilling may be required.

GEOPHYSICAL SURVEY RESULTS  
JR PROJECT

1. SUMMARY

VLF-EM results have outlined conductive trends lying in a northwest orientation. Conductor "A" shows the highest conductance in the area. It is interpreted as a double conductor at a moderate depth. The conductor system labelled "B" exhibits low to moderate conductance and shows a correlation with small magnetic highs. Both conductor systems may represent narrow veins of sulphide mineralization. There may be some magnetic pyrrhotite associated with conductor system "B". Short weak conductors are probably narrow and near surface, possibly due to alteration in fractures.

Two fault zones have been interpreted on the basis of VLF EM profile characteristics.

Isolated magnetic high anomalies in the area are believed to be caused by near surface local occurrences of magnetite.

The existence of interpreted faults should be investigated and their importance determined. A VLF EM survey perpendicular to the present grid across the interpreted faults is recommended. Geophysical priorities for expanded VLF EM and magnetic survey are systems "A" and "B".

2. SURVEY SPECIFICATIONS

2.1 Survey Parameters

- survey line separation - 100 meters
- survey station spacing - 10 meters
- base line direction - North-South
- survey lines were perpendicular to the base line
- readings taken using Seattle VLF transmitter
- survey totals:   VLF EM   - 11.0 kilometers  
                    Magnetics - 13.0 kilometers

## 2.2 Equipment Parameters

### VLF Electromagnetic Survey

- Geonics EM-16 used for all survey
- transmitting station: - Seattle, Washington
- in-phase (dip angle) and out-of-phase (quadrature) components measured in percent at each station
- direction faced: - easterly

### Magnetic Survey

- Geometrics G-856 magnetometer and G-856 automatic recording base station
- readings in gammas - base level 58,350 gammas
- field readings corrected to a datum using base station values

## 3. DATA

### 3.1 Calculations

- VLF Electromagnetic Survey
  - Fraser Filter values (after Fraser, 1969) were calculated for in-phase readings for all lines in the area
- Magnetic Survey
  - no calculations were carried out on magnetic data other than correction of diurnal magnetic variations to a datum using values recorded by an automatic recording magnetic base station

### 3.2 Presentation

- VLF Electromagnetic Survey
  - VLF EM in-phase readings plus calculated Fraser Filter values are presented in an appendix in the form of tables showing values located with respect to line number and station number
  - VLF EM in-phase and out-of-phase readings are presented in profile form on a plan map at a scale of 1:2,500
  - VLF EM Fraser Filter values are presented as contours on plan maps at a scale of 1:5,000
  - VLF EM Fraser Filter values are presented in the form of a 3-D plot as a visual aid

- Magnetic Survey
  - diurnally corrected magnetic data are presented in an appendix in the form of tables showing values located with respect to line and station number
  - magnetic data are presented in profile form on a plan map at a scale of 1:2,500
  - magnetic values are presented as contours on plan maps at a scale of 1:5,000
  - magnetic values are presented in the form of a 3-D plot as a visual aid
- Interpretation
  - significant results of the geophysical surveys are presented on a Geophysical Interpretation Map at a scale of 1:2,500

#### 4. INTERPRETATION

##### 4.1 Discussion of Results

The station spacing of ten meters enhanced the character detail of VLF EM anomalies but also allowed short wavelength noise to be seen. The noise is thought to reflect surficial features such as conductive overburden. The detail in the character of the profiles allowed detection of double conductors, not seen in the Fraser Filtered data because of its smoothing effect.

On this project topographic effects were evident but they did not interfere with the VLF EM interpretation. A valley running along the western edge of the grid produced a topographic effect which is seen as a positive bias when facing up hill and negative when facing down hill. A positive bias can be seen on the southwest conductor ("C") due to the operator facing uphill. Steep terrain on lines 5+00N and 6+00N did not translate into significant VLF EM topographic effects because the topographic changes were short and abrupt. Most of this effect of topography is filtered out when the Fraser Filter calculations are applied to the VLF EM in-phase data.

VLF EM and magnetic data were interpreted from the profile maps. The Fraser Filter contour map washed out the VLF EM trends too much to be useful in interpretation and the magnetic contour map was not sensitive enough to see small magnetic correlations with conductors. A significant magnetic trend was noted on the Geophysical Interpretation Map as "M1". Significant VLF EM trends were noted as "A", "B" etc.

#### 4.2 Conclusions

VLF EM results show a number of relatively short conductors (400 meters or less) trending in a northwest direction. Good profile character seems to suggest a geological, rather than an overburden cause for the strong VLF EM anomalies. The short wavelength, moderate to weak anomalies of generally low conductance indicate near surface conductive zones which are probably narrow. This may indicate fractures in the bedrock which are altered or perhaps mineralized or it may signify conductive overburden. Two fault zones have been interpreted on the basis of conductor offsets and terminations as well as VLF profile character change. A number of more important conductive trends have been labelled for more detailed consideration.

Conductor system "A" is a double conductor which shows a moderate amplitude response and exhibits higher conductance than other VLF EM features in the area. The approximate depth of this system "A" may be 50 to 75 meters. The conductors run into an interpreted fault at line 6+00N and from there continuation becomes inconclusive. It would appear that there are conductors to the east of lines 5+00N and 6+00N, possibly off area, and these may be the displaced portion of system "A". To the north the system pinches out or becomes deeper. Since no magnetic anomalies coincide with the conductors, system "A" may represent a double non-magnetic sulphide mineralized zone.

The conductor system labelled "B" shows low conductance and exhibits a moderate response amplitude. It is bounded on both ends by the interpreted faults and may be part of the weak conductors to the north and south labelled "B1" and "B2". Conductor "B" seems to split from a single conductor on line 6+00N to a double conductor on lines 5+00N and 7+00N. The in-phase responses shown by some profiles indicate that the system may have a large depth extent.

The association of systems "B, B1 and B2" was interpreted from similar magnetic correlations with the VLF EM conductors. System "B, B1 and B2" VLF EM Anomalies on lines 0+00, 3+00N, 5+00N, 7+00N, 8+00N, 9+00N and possibly on line 4+00N seem to correlate directly with small magnetic highs. The double magnetic response on lines 5+00N and 7+00N supports the interpretation of system "B" as a double conductor. A strong, local magnetic high on line 6+00N may have masked out the small magnetic response seen on adjoining lines. System "B" may represent a narrow sulphide vein containing magnetic pyrrhotite.

Conductor system "C" shows good response amplitude in the south but becomes weaker to the north. Profile character for lines 0+00 and 1+00N indicate a comparable depth extent to system "B". The lack of magnetic correlation suggests that pyrrhotite does not contribute to conductivity in this case.

The interpreted faults appear to have some connection to VLF EM conductor responses since the strongest responses are near the interpreted faults. This may be due to dilation near the interpreted faults allowing accumulation of minerals in the conductive zone as well as deposition within the interpreted faults themselves. If the fault interpretation is correct, conductive material within the interpreted fault zones would not be detected by the present survey because of the shallow angle of incidence between the present survey line and the interpreted faults.

An area on the western side of the grid, between the two interpreted faults, contains a broad magnetic anomaly. This broad magnetic anomaly may indicate the presence of deep seated basic or ultrabasic rock, possibly thrust closer to the surface between the two interpreted faults. This zone is labelled "M1" on the geophysical interpretation map.

Isolated magnetic high anomalies in the area are believed to be caused by near surface local occurrences of magnetite.

##### 5. RECOMMENDATIONS

The interpreted faults should be geologically investigated to determine their existence and to see whether faulting may have played a role in mineral emplacement both in the conductors shown by the present VLF EM survey and in the interpreted faults. In addition to the geological work, a limited VLF EM survey perpendicular to the present VLF EM coverage is recommended across the interpreted faults in order to verify their existence. Geological and geochemical information should then be correlated with the geophysical information obtained in this survey and priorities established for detail follow-up of the important VLF-EM conductors. If further exploration is warranted, a grid expanded further to the east is recommended for the purpose of additional VLF EM and magnetic survey.

Geophysical priorities for detail VLF EM and magnetic follow-up on the present grid are systems "A" and "B".

CERTIFICATE

I, Thomas Raymond Matich, Geophysicist of Surrey, British Columbia, Canada, hereby certify that:

1. I received a B.Sc. degree in Geophysics from the University of British Columbia in 1982.
2. I have been practising my profession since graduation.
3. I hold no direct or indirect interest in, nor expect to receive any benefits from, the mineral property or properties described in this report.

Date: December 18, 1986 Signed: Tom Matich

Vancouver,  
British Columbia

INTERPRETEX RESOURCES LTD.

TOTAL FIELD MAGNETIC DATA CORRECTIONS WORKSHEET

GRID: JR

file name: JR1MAG

DEFINITIONS:

- MAGPAC FIELD VALUE - Diurnally corrected data imported from MAGPAC program
- DATUM CORRECTION - correction from a variable datum value (in MAGPAC) to a constant datum value for the area.
- AVERAGE BASE VALUE - the variable datum value from MAGPAC (depending on average mag. level each day)

BASE STATION DATUM 58350 LINE # L-1400 N

OPERATOR ADJUST: 0

AVERAGE BASE VALUE 58339.6

STATIONS +ve = eastings, -ve = westings  
STATION INTERVAL: 10 m.

TOTAL FIELD MAGNETIC DATA CORRECTIONS WORKSHEET

GRID: JR

file name: JR3MAG

DEFINITIONS:

- MAGPAC FIELD VALUE - Diurnally corrected data imported from MAGPAC program
- DATUM CORRECTION - correction from a variable datum value (in MAGPAC) to a constant datum value for the area.
- AVERAGE BASE VALUE - the variable datum value from MAGPAC (depending on average mag. level each day)

TOTAL FIELD MAGNETIC DATA CORRECTIONS WORKSHEET  
GRID: JR  
file name: JR6MAG

DEFINITIONS:

- MAGPAC FIELD VALUE - Diurnally corrected data imported from MAGPAC program
- DATUM CORRECTION - correction from a variable datum value (in MAGPAC) to a constant datum value for the area.
- AVERAGE BASE VALUE - the variable datum value from MAGPAC (depending on average mag. level each day)

BASE STATION DATUM 58350 LINE # L-6+00 N

OPERATOR ADJUST: 0

AVERAGE BASE VALUE 56951.9

STATIONS +ve = eastings, -ve = westings  
STATION INTERVAL: 10 m.

TOTAL FIELD MAGNETIC DATA CORRECTIONS WORKSHEET  
GRID: JR  
file name: JR9MAG

DEFINITIONS:

- MAGPAC FIELD VALUE - Diurnally corrected data imported from MAGPAC program
- DATUM CORRECTION - correction from a variable datum value (in MAGPAC) to a constant datum value for the area.
- AVERAGE BASE VALUE - the variable datum value from MAGPAC (depending on average mag. level each day)

BASE STATION DATUM 58350 LINE # L-9+00 N

OPERATOR ADJUST: 0

AVERAGE BASE VALUE 58339.6

STATIONS +ve = eastings, -ve = westings  
STATION INTERVAL: 10 m.

TOTAL FIELD MAGNETIC DATA CORRECTIONS WORKSHEET

GRID: JR

file name: JRBLMAG

DEFINITIONS:

-MAGPAC FIELD VALUE - Diurnally corrected data imported from MAGPAC program

-DATUM CORRECTION - correction from a variable datum value (in MAGPAC) to a constant datum value for one area.

-AVERAGE BASE VALUE - the variable datum value from MAGPAC (dependent on average map level band cov)

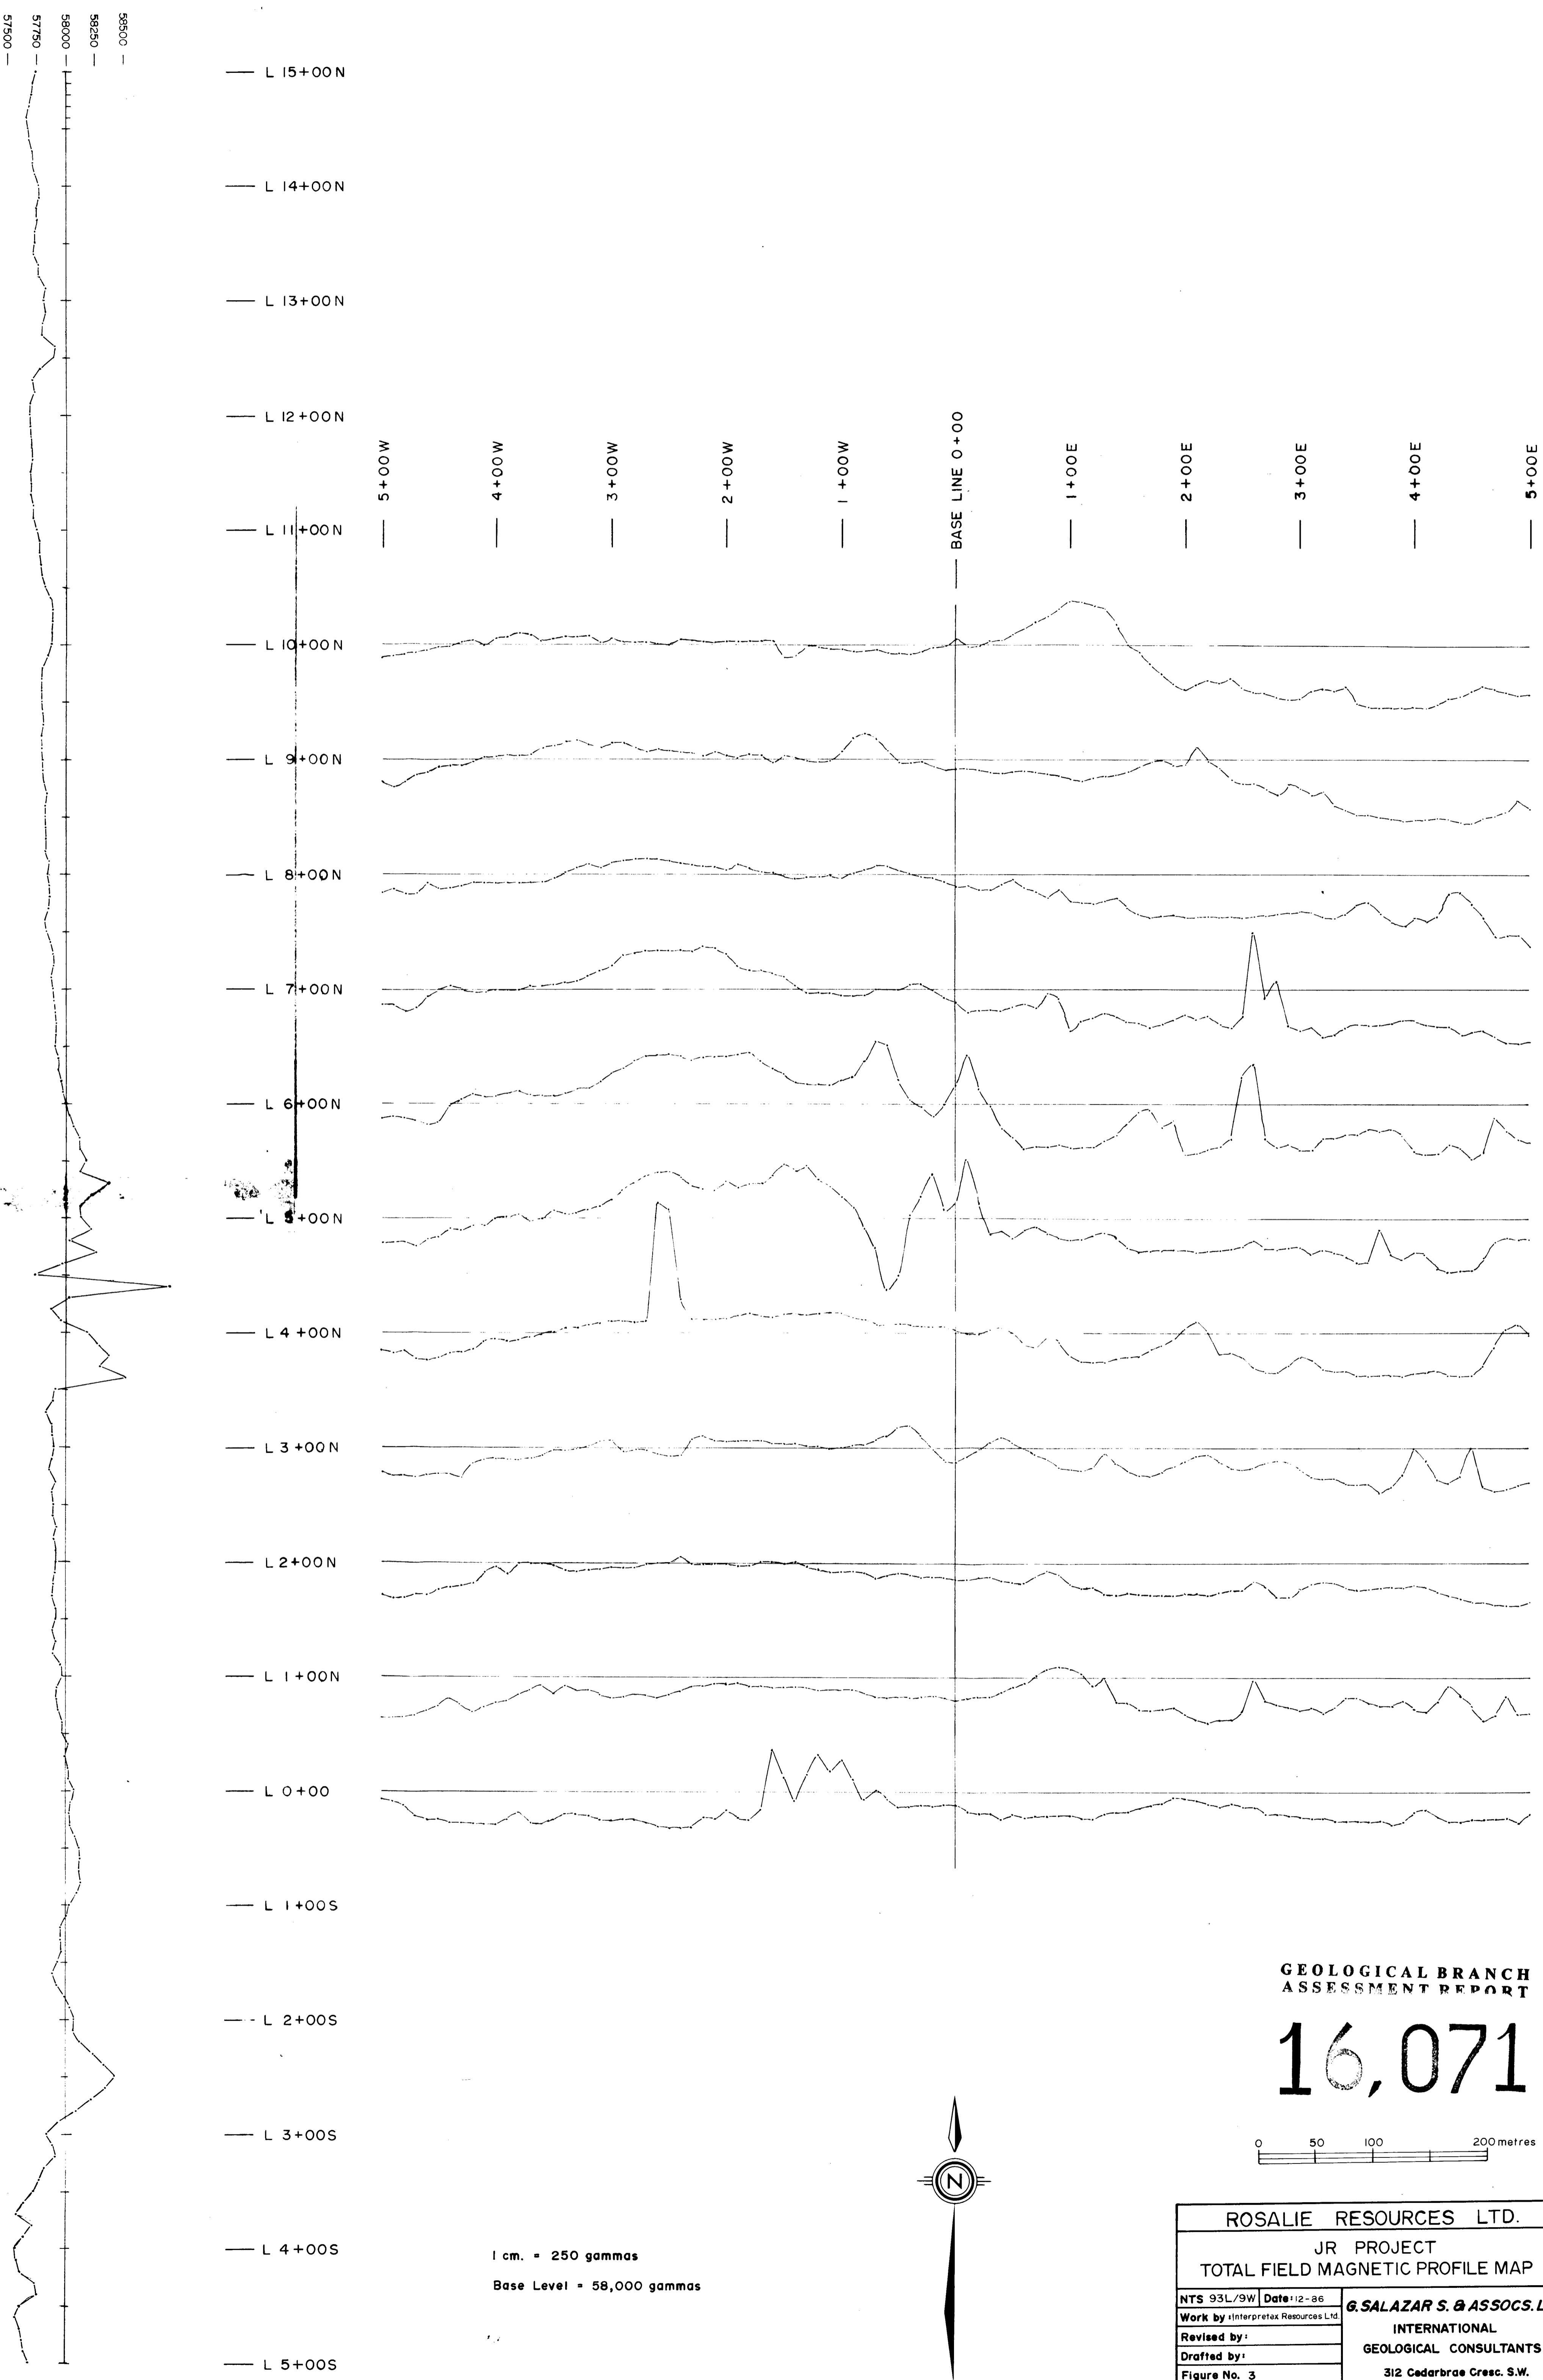

BASE STATION DATUM	58350	LINE #	BLW-0400-4
OPERATOR ADJUST:	0		
AVERAGE BASE VALUE	58339.6		
STATION INTERVAL:	10 m.	STATIONS	+ve = northings, -ve = southings
STATION	FINAL VAL.	DATUM	MAGPAC
		CORRECTN	FIELD VAL.
