## INTRODUCTION

The Marie Property is located in central Graham Island in the Queen Charlotte Islands. It is comprised of 6 mineral claims (63 units) which cover about 1725 hectares. The claim block is within sight of the City Resources (formerly Consolidated Cinola Mines Ltd.) Property located just to the east. The initial staking was done in May 1978 based on the results of prospecting and reconnaissance work which showed that the alteration and stratigraphy is similar to the City Resources Property. Follow up work showed broad arsenic geochemical anomalies associated with silicified Tertiary volcanics.

Detailed mapping and sampling at a 1:1000 scale was completed in August 1987 on an area located just NW of Sheila Lake. The objective of the program was to further delineate alteration patterns and geochemical anomalies to target likely areas for drilling.

## PREVIOUS WORK

Parts of the present property were first staked in May of 1978 after prospecting work and reconnaissance geochemical sampling in 1977 and early 1978 had indicated an area around Marie and Sheila Lakes to have strong zones of silicification associated with sulfide mineralization and highly anomalous gold, arsenic, and mercury geochemistry. Additional staking was done in June 1978, August 1978, October 1978, April 1979, August 1979, and August 1980 as work progressed on the property. In

July of 1982 a decision was made to abandon and restake the entire property in order to simplify maintenance of the claims which had six different Record Dates. All claims were formally abandoned and the M (#1 - #6) claims staked covering the areas of interest. A new Record Date of August 4, 1982 was established for the entire property.

The Property was optioned by Chevron Standard Limited in 1978 and in 1979 a contract was given to JMT Services Corp. to complete a program of geological mapping and grid geochemistry. Mapping showed that large portions of the claim block are underlain by Tertiary volcanics of the Masset Formation, lying unconformably on poorly exposed Mesozoic argillites and sandstones cut by diorite. Zones of sulfide mineralization associated with weak to strong silicification and bleaching were mapped within both the volcanics and sediments at a number of locations. Large arsenic, mercury and gold soil anomalies were shown to be associated with these sulfide zones. The Tertiary unconformity was believed to play an important role in the control and localization of mineralization.

In October of 1979, Chevron mobilized a percussion drill to the Charlottes for work on two other properties, but made a decision to drill a series of 6 holes along a logging road which cut through one of the anomalous areas identified previously. Two of the holes encountered 60 foot intercepts of anomalous gold-arsenic geochemistry which are of considerable interest but no follow-up work was ever done.

In 1980 Chevron geologists completed a limited program of detailed geological mapping and rock chip sampling in a small area northwest of Sheila Lake. A number of light coloured rhyolitic dykes containing sulfides were mapped in the areas with anomalous geochemistry. Chevron conducted additional geological and geochemical surveys in the northwest part of the property in 1980 and 1981 prior to terminating their option in 1982. No work programs have been done on the property since 1981.

In October 1986, the M1, M3 and M6 claims were staked by Lawrence Hewitt and Barron International Resources Inc. has obtained an option on the M1 through M6 claims.

#### LOCATION, TOPOGRAPHY AND ACCESS

The property is located on central Graham Island, in the Queen Charlottes, some 740 km northwest of Vancouver (figure 1). The claims are situated on the upper drainage of Gold Creek which includes the rolling terrain between Sheila, Pam and Marie Lakes and the steep hill lying immediately west of Sheila Lake. Gold Creek Valley is 1500 metres wide east of Marie Lake but widens to an area of flat terrain between Marie, Pam and Sheila Lakes. This low lying area is variably covered in hemlock-spruce forest and cedar-cypress swamps with the steeper slopes being heavily timbered with mature hemlock-spruce. A minor amount of second growth, about fifteen years old, covers the southeast portion of the claim block.

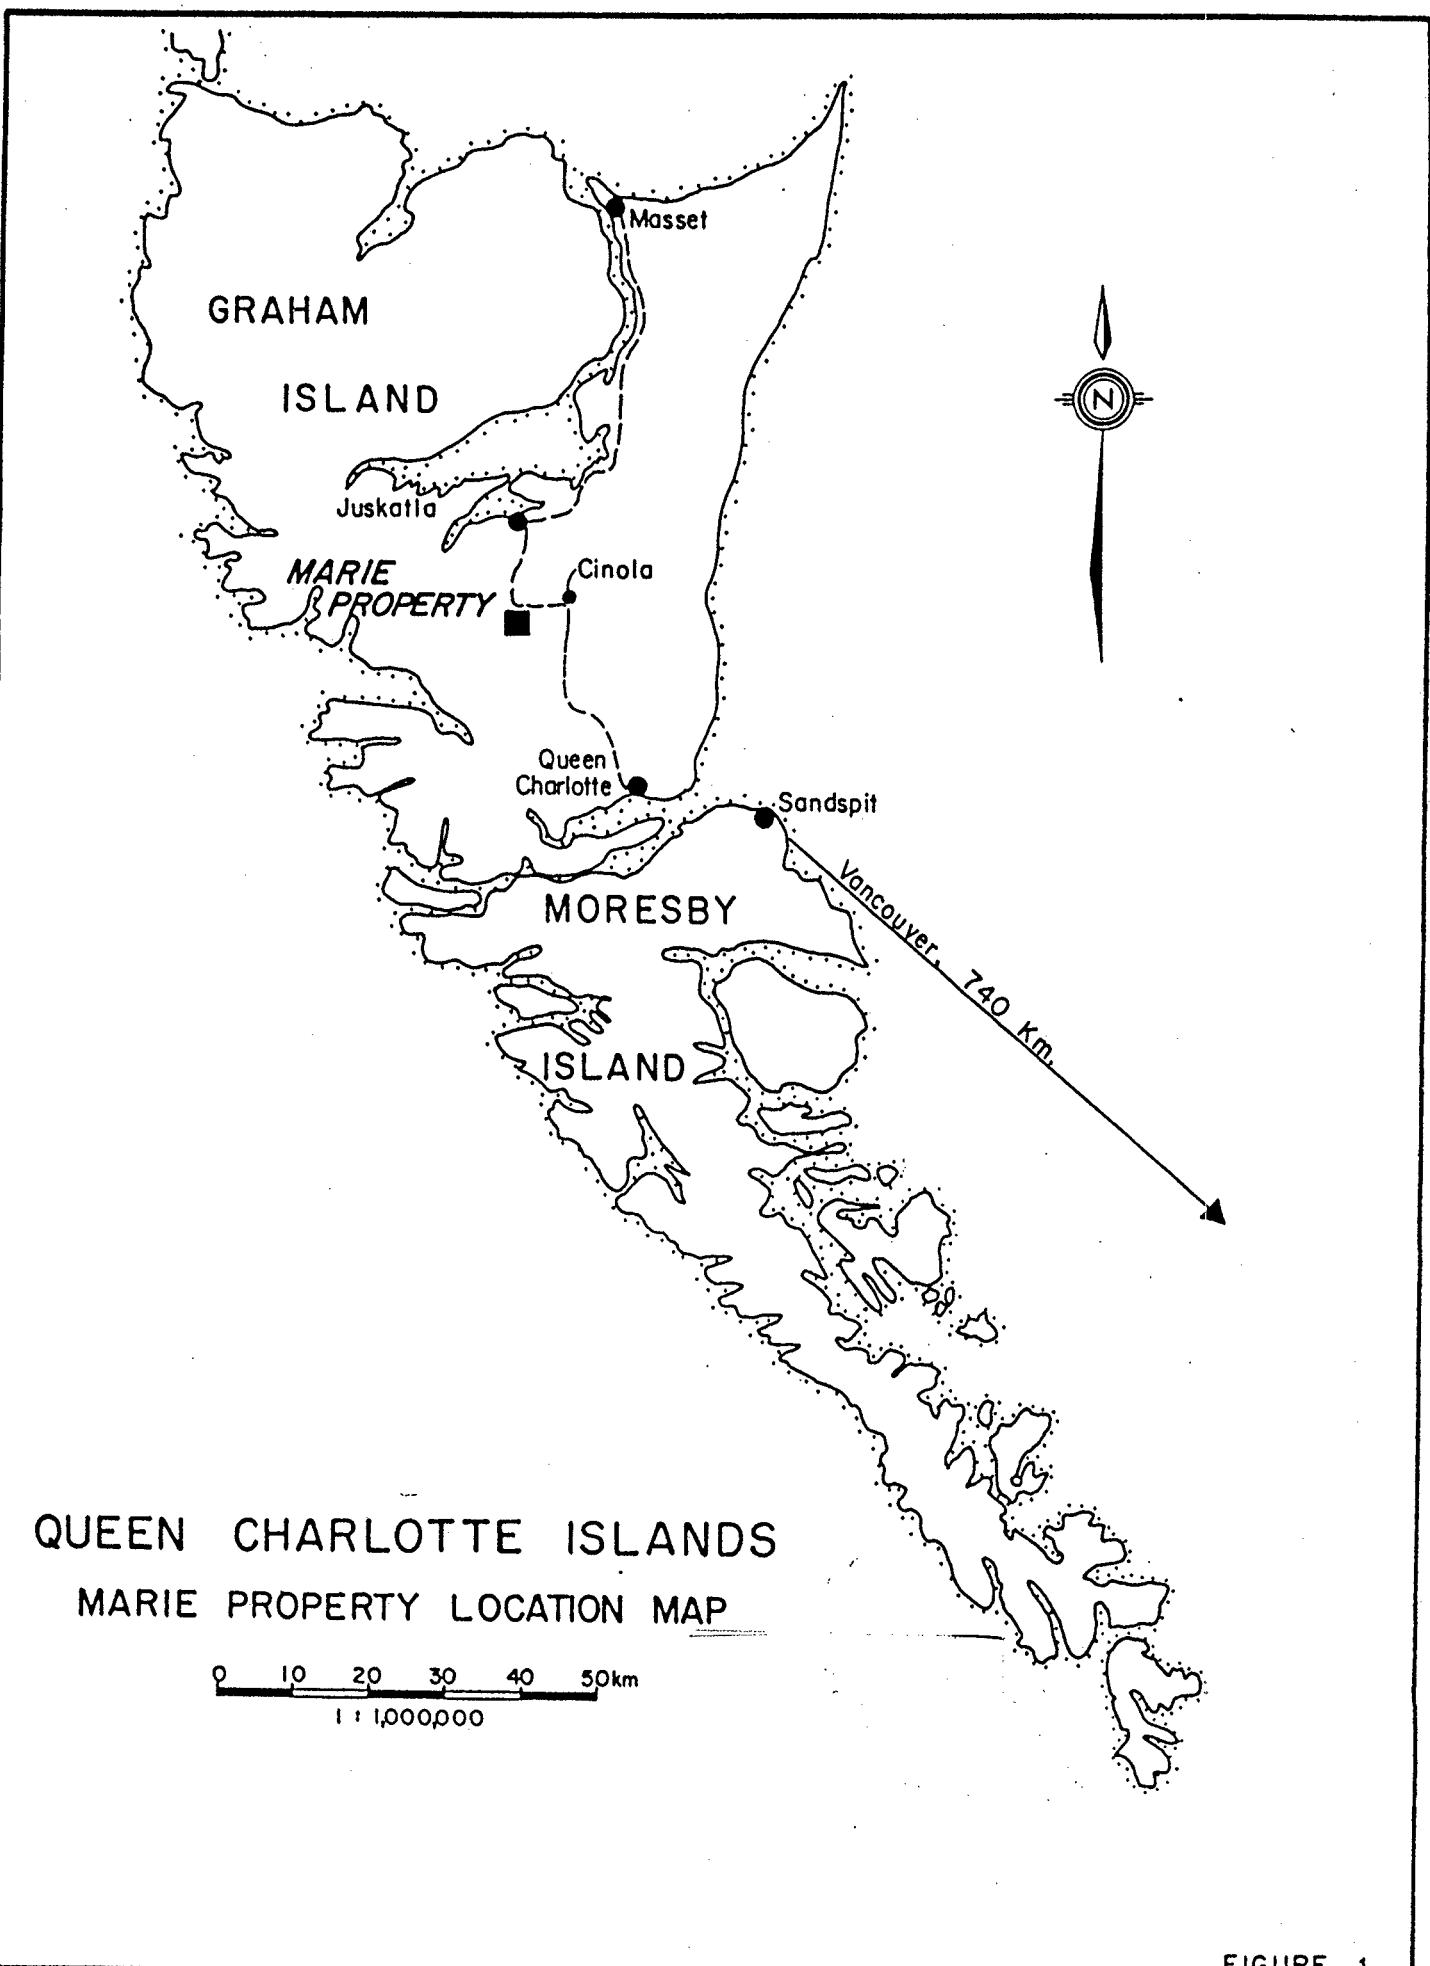

Access to the property is excellent. The Queen Charlotte

Islands may be reached by daily Canadian Airlines jet service from Vancouver, or twice weekly ferry service from Prince Rupert. The property itself is accessible by road by driving south from Juskatla along MacMillan Bloedel's main haulage road for 20 kilometres to Branch 30 which cuts through the centre of the property to the east side of Sheila Lake. Recent logging (Spring 1987) was completed on the hill just west of Pam Lake allowing access by road to all areas of the claim block. The property area may also be reached by going north through Queen Charlotte City along the main haulage road.

#### MINERAL CLAIMS

The property consists of the M #1 - #6 mineral claims described below and shown on accompanying claim map (figure 2).

<u>NAME</u>	<u>RECORD NO.</u>	<u>UNITS</u>	<u>RECORD DATE</u>	<u>EXPIRY YEAR</u>

## GENERAL GEOLOGY

The Queen Charlotte Islands are part of the Insular Belt of the Canadian Cordillera. They are separated from the Pacific Ocean floor by the Queen Charlotte Transform Fault. The area is included within the Pacific Continental Shelf physiographic region and has been divided into the Queen Charlotte Ranges, Skidegate Plateau and Queen Charlotte Lowlands. The boundaries between the physiographic units follow major northwest trending fault zones. The Queen Charlotte Ranges are underlain by a varied assemblage of mainly Mesozoic volcanic, plutonic, sedimentary formations with a cover of Quaternary drift. The area of main interest for precious metals is near the faulted boundary of the Skidegate Plateau and Charlotte Lowlands. The general geology of the Queen Charlotte Islands has been mapped and reported on by A. Sutherland-Brown in British Columbia Department of Mines Bulletin No. 54 (1968).

## LOCAL GEOLOGY

A synopsis of local geology is shown on Figure 3. A dominant feature is the flat lying Tertiary unconformity between acid to intermediate Masset volcanics and pyroclastics and underlying marine sediments of Mesozoic area. A small dioritic stock cuts the sediments in the southern part of the property and has given rise to narrow hornfels zones along its contacts. The sedimentary succession consists of medium to thick bedded shales and calcareous sandstones of the Haida Formation, with dip angles

varying from moderate to steep. The sediments and volcanics are cut by a number of light coloured sulfide bearing rhyolitic dykes in the areas examined. Two strong sub-parallel northerly trending faults cut through the claim area. These could be important controls of mineralization on the property and may have produced permeability needed to channel mineralized solutions.

Outcrops examined in the previous drilled area are variably silicified, pyrite mineralized and veined with chalcedonic veinlets. Drill holes were spotted in the general area of coincident hydrothermal alteration and anomalous geochemistry but the areas designated as Target No. 1, a faulted extension of the drilled area, and Target No. 2, a concentrically altered area were not drill tested because of difficult access. The setting of mineralization on the Marie Property is similar to the City Resources Property (formerly the Specogna Property of Consolidated Cinola Mines Ltd.) where reserves of 41 million metric tonnes of 0.067 oz/tonne gold have been reported (1982/83 Canadian Mines Handbook). Mineralization occurs along a faulted contact between Haida shale and overlying volcaniclastics in association with rhyolite dykes or sills.

#### TARGET No. 2

##### a) Geology (see map in pocket)

The 1987 exploration was carried out on the Target No. 2 area of Figure 3. This area of the claim block is underlain by Tertiary age felsic to intermediate composition volcaniclastic

rocks of the Masset Formation. At the NW edge of the mapped area, Haida shale and siltstone outcrops occur. These lie unconformably below the Tertiary volcanioclastics. The unconformity appears in outcrop in a few localities and can be traced fairly easily for some distance due to subtle changes in topography and vegetation.

The Tertiary volcanioclastic rocks consist of alternating units of rhyolite dacite welded crystal tuffs and tuff-breccias and dacite-andesite cobble breccias. The more felsic units have a greater pyrite content and stronger silicification. Fragments of Haida sediments are quite common in the volcanic breccias. Several bedding attitudes taken indicate a strike of approximately  $020^{\circ}$  with the units dipping 45 to 70 degrees to the northwest. Andesite dikes and sills occur throughout the Tertiary volcanioclastic rocks. The diorite stock located to the west of the mapped area could be a possible source for the intrusives.

#### b) Alteration

Two broad zones of pyritic alteration with silicified centres occur in the mapped area. Silicification varies in intensity with the more strongly silicified areas containing veinlets of chalcedony. Pyrite occurs as both fine to medium grained disseminated and as thin veinlets with greater than 20% pyrite occurring in some areas. Strong tourmalinization associated with intense bleaching was found at three localities of Target No. 2. The tourmaline alteration appears to be related

to faulting and consists of radiating crystal groups in strongly bleached and silicified rock.

The alteration occurs in both the volcaniclastic rocks and in the calcareous shaly sediments located at the NW edge of the mapped area. Altered zones are bounded in the southeast by a large steeply dipping fault that trends NE.

c) **Geochemistry** (see map in pocket)

In 1987, 376 soil samples were collected from the reddish brown oxidized A-horizon. Sample depths varied from 3" to 8" and the soils were deposited in a 4" x 10" gusset kraft paper soil sample bag. The soils were collected at 50 metre intervals on a grid with lines spaced 50 metres apart. The soil samples were analyzed for 38 different elements by Chemex Labs Ltd..

The sample results indicated strongly anomalous arsenic (As) values in the soils. Background values for arsenic are 0-5 ppm with values of 100+ ppm considered strongly anomalous. The soil survey outlined a large area of strongly anomalous arsenic (100 samples were  $\geq$  100ppm As) starting from the large fault in the SE border of the grid and fanning out for approximately 600m to the NW. The arsenic anomaly may continue to the NE however glacial tills become very thick at the lower slopes and mask the geochemistry. The arsenic anomaly follows the zone of strong silicification and pyritization quite closely as can be seen by comparing the two maps in the pockets (figure 4 and 5).

89 rock chip samples were collected during the 1987 program. These samples were taken from surface outcrops or sub-outcrops of

mineralized rock using a rock hammer and were made up of 3 to 20 small rock chips sufficient to fill a standard gusset kraft paper soil bag. The rock samples were analyzed for gold (Au) by Chemex Labs Ltd. using the neutron activation analysis method.

#### DISCUSSION AND RECOMMENDATIONS

The geological setting in the Marie Lake area is similar to the City Resources low grade, high tonnage property located several kilometres to the east. This type of deposit is a tabular, stratabound, disseminated micron gold deposit located in a permeable and reactive host rock. Hydrothermal fluids driven by a heat source such as underlying volcanic activity, dissolve gold in surrounding rocks and transports it via high angle, deep-seated faults towards the surface. When a permeable reactive rock is encountered the fluids move laterally through the rock depositing the gold as a result of chemical or thermal changes in the fluids. Typical alteration consists of intense silicification and pyritization which can be above, below or with the gold mineralization. These deposits normally have high Au:Ag ratios and are enriched in Hg-As-Sb-Ba-Tl.

In the Target No. 2 area the alteration patterns strongly resemble the above model. A zone of strong silicification in the Tertiary Masset volcanics is bounded to the southeast by a large fault which is possibly the channel way for hydrothermal fluids. The large diorite stock located to the southeast could provide the heat source with the underlying Haida calcareous

sediments providing the host rock. Although the gold geochemistry is low, strong arsenic and mercury anomalies in the silicified zones of this area were discovered in past exploration.

The alteration patterns in the Target No. 2 area indicate the possibility of a subsurface, stratabound, low grade gold deposit. Due to the presence of pyrite in the alteration assemblage it is recommended that an I.P. and Resistivity geophysical survey be done to map the subsurface limits of alteration. A V.L.F. survey should also be completed to map the faults and other structures important in controlling the gold deposition.

Respectfully submitted,

D.R. Bennett, B.Sc.

J.S. Christie, Ph.D.
