Report on the 1987 Drill Program
Mt. Sicker Property

1. Introduction

This report summarizes the results of the 1987 spring drill program on Minnova's Mt. Sicker property. A total of 16 diamond drill holes (3217.2 meters) were completed by F. Boisvenu Diamond Drilling Ltd. of Vancouver. The drilling commenced on May 25, 1987 and was completed on July 16, 1987.

a. Location and Access

The Mt. Sicker property is located 40 km and 10 km north of Victoria and Duncan respectively (Figure 1). An extensive system of logging roads from the Island Highway provide excellent access to the property. Topographic relief is moderate with elevations ranging from 150 to 700 meters above sea level. The property is covered by a mixed forest of Douglas fir, alder and cedar. Active logging is currently underway in several parts of the property.

b.Property Status

The Mt. Sicker property consists of 4 contiguous options (Postuk-Fulton, Peppa, Lieberman, Canamera) and CFC claims for a total of 198 units . The claims listed in Appendix I and outlined in Figure 2 have been subdivided into the Rocky, Lenora and Cu Canyon groups.

c. History

Two former producers - the Lenora and Tyee mines occur on the Mt. Sicker property. These deposits were discovered in 1898 and were largely mined out by 1909 although they were worked periodically until 1947. A total of 300,000 tons grading 3.31% Cu, 7.51% Zn, 2.75 oz./ton Ag and 0.13 oz./ton Au were recovered from these 2 mines. Recent exploration on the property has been done by Duncanex, Mt. Sicker Mines and Serem in the vicinity of the former mines and the Postuk-Fulton and NE Copper showings. Minnova Inc. (formerly Corporation Falconbridge Copper) has been active of the property since 1983. We have carried out an integrated exploration program consisting of geological, geochemical and geophysical surveys which have been followed up by diamond drilling. All aspects of this continuing program have been aimed at

discovering a polymetallic volcanogenic massive sulphide deposit.

2. Geology

a. Regional Geology

The Mt. Sicker property is located in the Cowichan-Horne Lake uplift which is one of 3 fault-bounded areas that expose the Paleozoic Sicker Group on Vancouver Island (Figure 1). Muller (1980) subdivided the Sicker Group, as follows, in order of increasing age:

1) Buttle Lake Formation - consists of recrystallized crinoidal limestone interbedded with calcareous siltstone and chert
2) Sediment - Sill Unit - thinly bedded to massive argillite, siltstone and chert interlayered with diabase sills
3) Myra Formation - basic to rhyodacitic banded tuff, breccia and lava with interbedded argillite, siltstone and chert
4) Nitinat Formation - basaltic lavas and agglomerates with minor to massive banded tuff layers

Cretaceous sediments of the Nanaimo Group unconformably overly the Sicker group; the contact is commonly marked by a basal conglomerate containing volcanic fragments derived from the Sicker Group.

The structure of the Sicker group is characterized by southwest verging, asymmetric and vertical, open and isoclinal folds (Muller, 1980). West - northwest and northeast trending faults disect the Sicker Group of the Cowichan-Horne Lake Uplift into numerous fault blocks. Movement along those faults is interpreted to have been mostly Tertiary in age (Muller, 1980). Metamorphic grade ranges from subgreenschist to greenschist.

b. Geology of the Mt. Sicker Property

The Mt. Sicker property is underlain by Sicker Group volcanic rocks, Nanaimo Group sediments and dioritic intrusions of possible Triassic age (Figures 3a, b). The Sicker Group can be subdivided into the Myra and Nitinat formations. The Myra formation consists of thick units of felsic and subordinate mafic pyroclastic/flow rocks with minor ash, argillaceous sediment and chert. The Lenora-Tyee massive sulphide deposits occur within the Mine package which is a distinct well-bedded, 70 meter thick succession of quartz +/- feldspar crystal tuffs, local felsic flows, fine felsic ash and minor chert and argillite.

The Lenora-Tyee deposits are considered to be the stratigraphic equivalent of Westmin's Myra-Lynx deposits.

The Nitinat formation is restricted to the east end of the property and is well exposed along the Island Highway. The formation consists of epidotized pyroxene and/or plagioclase porphyritic andesitic-basaltic flows, flow breccias and debris flows. The Myra-Nitinat contact is interpreted to be the stratigraphic equivalent to the "H-W Horizon" at Buttle Lake and as such is considered as a prime exploration target.

The structure of the Mt. Sicker property is dominated by a large asymmetric, west-northwesterly trending, shallow west-plunging anticline. The fold axis is interpreted to lie 300m north of the Lenora-Tyee deposits. The axial plane of the anticline is reflected by a pervasive moderately to intensely developed, vertically dipping foliation. Small drag folds associated with the Mt. Sicker anticline occur at NE Copper and Lenora-Tyee.

3. Work Completed

Fifteen diamond drill holes were completed and one hole was deepened for a total of 3217.2 meters. Lithogeochemical samples were taken routinely throughout the holes and analysed for major and trace elements (SiO_2, TiO_2, Al_2O_3, CaO, Na_2O, K_2O, MgO, MnO_2, FeO_3, Pb, Ba, Cu, Zn) at Min-En Laboratories in Vancouver. Mineralized sections were analysed for Cu, Zn, Ag and Au. The drill core is stored at 6722 Lakes Road, Duncan, B. C.

4. Drill Hole Summary and Results

Drill hole locations are shown in plan view on Figures 1 and 2. A brief summary of each hole is presented below whereas detailed descriptions are given in Appendix II.

CM-I

Hole CM-I tested two weak VLF conductors located 100 meters northwest of pyrite-chalcopyrite stringer mineralization exposed at the old Copper Canyon workings on the west side of the Chemainus River. A 7.7 meter wide pyritic stringer zone was intersected but metal values of this zone are low.

Summary Log

0 - 37.8	-	overburden
37.8-65.6	-	dacitic tuffs, crystal tuffs
65.6-69.7	-	andesitic tuff
69.7-175.6	-	dacitic tuffs, crystal tuffs
		86.5 - 94.2 - pyritic stringer zone
175.6 - EOH		

CM-2

Hole CM-2 tested a strong IP chargeability anomaly and the stratigraphy above a pyrite-chalcopyrite stringer zone. The hole was also designed to give a stratigraphic section of a zone of felsic to intermediate volcanic rocks which are believed to be correlative with the rocks hosting Abermin's Coronation zone. A predominantly andesitic package of tuffs and crystal tuffs was intersected and the abundant disseminated pyrite mineralization accounted for the IP anomaly. No zones of significant mineralization were intersected.

Summary Log

0 - 7.3	-	overburden
7.3 -54.9	-	andesite tuff, crystal tuff
		51.0 - 54.9 - py stringers, 3-15% py
54.9-59.0	-	QFP crystal tuff
59.0-70.3	-	andesite tuff, crystal tuff
70.3-72.1	-	siliceous felsic tuff
72.1-124.7	-	andesite tuff, crystal tuff
124.7-139.6	-	diorite
139.6-168.0	-	andesite tuff, crystal tuff
168.0-173.0	-	rhyodacitic tuff
173.0-187.0	-	andesite tuff
187.0-193.9	-	rhyodacitic tuff
193.9-EOH		

CM-3

Hole CM-3 was drilled to test the stratigraphy that could be equivalent of Abermin's Coronation Zone Horizon. The hole was collared in a QP flow or crystal tuff and then intersected a sequence of andesitic fragmental rocks. The hole ended in a diorite. The felsic, quartz-eyed rhyolites which host Abermin's mineralization were not intersected.

Summary Log

0 - 7.9	-	overburden
7.9 -24.1	-	QP flow or crystal tuff; fault gouge, moderate to strong sericite
24.1-49.1	-	andesite tuff, crystal tuff
49.1-70.1	-	andesite-basalt volcanic breccia
70.1-78.7	-	diorite
78.7-91.0	-	andesite volcanic breccia
91.0-114.0	-	diorite
114.0 - EOH		

CM-4

Hole CM-4 is the continuation of Canamera hole 86-5. The hole was deepened to test for the continuation of zinc mineralization in hole 85-3 which was collared 200 meters to the east. A thin graphitic argillite was intersected but there are no associated massive sulphides.

Summary Log

0 - 218.3	-	Logged previously
218.3 - 259.3	-	Felsic to intermediate crystal tuffs, weak chlorite
259.3 - 271.3	-	Felsic volcaniclastic - contains lithic fragments including argillite, matrix: weakly sericitic
271.3 - 272.35	-	Chert breccia/chert; 1-2% py as veinlets
272.35 - 272.7	-	Graphitic argillite and chert; 1-2% py
272.7 - 274.8	-	Felsic ash - intense sericite
274.8 - 289.95	-	Andesite ash and crystal tuff - weak epidote
289.95 - 312.7	-	Diorite

312.7 - EOH

CM-5

Hole CM-5 tested the extent of zinc stringer mineralization in hole 85-3, located approximately 100 meters to the east. A 16.2 wide zone of cherty argillite was intersected. No zones of significant economic sulphide content were encountered in the hole.

Summary Log

0.16.5	-	overburden
16.5 - 33.7	-	andesite tuff, crystal tuff
33.7 - 40.7	-	quartz-eye crystal tuff - fault zone
40.7 - 48.8	-	andesite lapilli tuff - tuff
48.8 - 59.8	-	rhyodacite crystal tuff
59.8 - 60.0	-	cherty argillite, 3-5% py
60.0 - 102.8	-	rhyodacite crystal - lithic tuff
102.8 - 119.0	-	argillite/cherty argillite, 3-5% py
119.0 - 140.3	-	andesite crystal tuff
140.3 - 147.8	-	diorite
147.8 - EOH		

CM-6

Hole CM-6 was drilled 150 meters east of hole 85-3 to test the strike extent of the argillite and zinc stringers intersected in that hole. A thin argillite was intersected in CM-6 near the lower contact of a diorite dike. The argillite is underlain by an altered felsic ash to crystal tuff. The Nanaimo sediments occur at the bottom of the hole giving a near vertical to steep northerly dip for the Nanaimo-Myra contact.

Summary Log

0 - 4.0	-	Overburden
4.0 - 31.75	-	Andesite tuff - weak chlorite - epidote
31.75 - 34.8	-	Felsic crystal tuff - pervasive chlorite, epidote

34.8 - 37.5	-	Diorite
37.5 - 42.45	-	Andesite crystal tuff - weak chlorite, epidote
42.45 - 46.45	-	Diorite
46.45 - 60.3	-	Andesite ash/lapilli tuff - weak chlorite
60.3 - 108.2	-	Diorite
108.2 - 108.25	-	Argillite
108.25 - 122.0	-	Felsic ash/crystal tuff 108.25 - 113.3 Intense sericite, 1% py, fault gouge 113.3 - 122.0 Moderate chlorite & sericite
122.0 - 155.0	-	Andesite ash and felsic crystal tuff - weakly chloritic
155.0 - 166.4	-	Nanaimo sediments - conglomerate, fault contact at 155.0 - 156.7
166.4 - EOH		

MTS-33

Hole MTS-33 was drilled to evaluate shallow level IP and lithogeochemical anomalies and the Myra-Nitinat contact. The hole intersected andesitic crystal tuffs with variable amounts of epidote patches. Pyrite content in these units was sufficient to explain the IP chargeability anomalies. The Myra-Nitinat contact was not intersected suggesting that the hole was drilled on the north limb of the Mt. Sicker anticlinal structure.

Summary Log

0 - 6.1	-	Overburden
6.1 - 96.0	-	Andesite crystal tuff with 5-10% epidote patches
96.0 - 104.25	-	Felsic tuff - chloritic, 5% py
104.25 - 345.1	-	Diorite with mafic, carbonate-rich dykes
345.1 - 374.5	-	Andesite crystal tuff/ash - pervasive epidote, weak to moderate chlorite; 2-3% pyrite
374.5 - 381.5	-	Felsic to intermediate crystal tuff - pervasively chloritic; 5% py
381.5 - 382.7	-	Andesitic ash
382.7 - 390.75	-	Andesite crystal to lapilli tuff; moderate epidote, weak chlorite

390.75 - 427.4		Felsic to intermediate crystal tuff - moderate chlorite-epidote, 3-5% pyrite
427.4 - 565.6	-	Andesite ash/crystal tuff with mafic + Q F P dykes. 428.5 - 437.0 10% dissem. py. 437.0 - 449.6 3-5% pyrite
565.6 - 603.6	-	Felsic ash/crystal tuff - moderate chlorite, 1-2% pyrite
603.6 - 625.1	-	Andesite crystal tuff - weak patchy epidote
625.1 - EOH		

MTS - 35

Hole MTS-35 was drilled to evaluate the extent and significance of zinc stringers intersected in hole MTS-30. Only minor sulphide mineralization was noted in the felsic volcanic rocks of the central mine package. The actual target may have been dilated by the diorite which was a lot thicker than expected.

Summary Log

0 - 0.6	-	overburden
0.6 - 198.8	-	diorite
198.8 - 202.8	-	fault gouge - sericitic
202.8 - 223.5	-	andesite tuffs
223.5 - 230.2	-	dacite tuff with 5-15% py at 223.5 - 224.7
230.2 - 258.5	-	rhyodacite quartz eye crystal tuff
258.5 - 266.7	-	andesite/dacite tuff
266.7 - EOH		

MTS-37

Hole MTS-37 tested the extent of stringer mineralization noted in hole MTS-24. A wide zone of stringer-type mineralization which assayed 400 ppm Cu over 22.8m is hosted in felsic weakly sericitic tuffs.

Summary Log

0 - 2.1	-	overburden
2.1 - 131.4	-	Felsic Tuffs with minor andesite crystal tuff and diorite dikes - Mine Package, weakly sericitic. 22.4 - 33.6 - 2-5% py 39.5 - 62.3 - 2-5% py, tr-1% cp; (400 ppm Cu over 22.8m).
131.4 - 139.3	-	Lenora Fault zone
139.3 - 142.5	-	Dacite-rhyodacite and andesite tuff, weak sericite/chlorite, 1-3% py
142.5 - 155.3	-	Tonalite dike
155.3 - 225.6	-	Dacite-rhyodacite tuff with minor andesite tuff tuff moderae chlorite-sericite; 1-3% py
225.6 - 226.2	-	Tonalite dike
226.2 EOH		

MTS-38

Hole MTS-38 tested the extent of zinc mineralization in the Mona shaft area; located 1.2 km east of the Lenora mine. A 1.5 meter thick pyritic ash which assayed 288 ppm Cu and 1500 ppm Ba was intersected. Bedding plane measurements suggest a shallow southerly dip which is consistent with the bedding noted in the surface trenches. This pyritic unit is possibly exhalative and warrants further follow-up drilling.

Summary Log

0 - 4.9	-	overburden
4.9 - 44.95	-	Diorite
44.95 - 52.25	-	Chert/Silicified Ash
52.25 - 74.95	-	Felsic Ash with chert fragments and beds. 68.75 - 70.1 - 2-3% py, tr cp; as veinlets/stringers 73.1 - 74.1 - 10% py, tr cp - stringers (0.37% Zn, 140 ppb Au/1.0m)

74.95 - 80.4	-	Quartz-phyric Crystal Tuff - sericitic
80.4 - 81.9	-	Pyritic ash with chert and qtz-phyric fragments 20-25% v.fgr. pyrite (288 ppm Cu, 17 ppm Zn, 1500 ppm Ba, 50 ppb Au/1.5m)
81.9 - 156.6	-	Felsic to Intermediate Ash 98.8 - 121.8 - moderately sericitic 131.4 - 156.6 - intense sericite-silica
156.6 - 179.4	-	Intermediate Ash Tuff
179.4 - 182.1	-	Mafic Dike
182.1 - 224.3	-	Intermediate Crystal Tuff/Ash - weakly chloritic
224.3 EOH		

MTS-39

Hole MTS-39 tested the new "Southern Horizon" which is thought to correlate with the Lenora mine sequence. Two zones of cherty argillite were noted. The units underlying these argillites are crowded quartz +/- feldspar crystal tuffs which are similar to those seen at the Lenora mine. No significant sulphides were intersected in MTS-39.

Summary Log

0 - 5.2	-	overburden
5.2 - 28.6	-	Diorite
28.6 - 45.25	-	Andesitic lapilli tuff and intermediate tuff - weakly chloritic; tr-5% py, tr cp.
45.25-46.3	-	Cherty argillite and chert; 3-5% py
46.3 - 59.6	-	Feldspar-quartz crystal tuff - weakly sericitic, 1-3% py
59.6 - 60.35	-	Argillite/cherty argillite; 1-8% py
60.35 - 61.3	-	rhyodacitic Q F P crystal tuff moderately sericitic, tr py.
61.3 - 74.8	-	Fault zone in felsic tuffs - strongly chloritic and sericitic
74.8 - 86.1	-	Felsic tuffs
86.1 - 93.8	-	Feldspar-phyric dike/flow - moderately sericitic
93.8 - 99.8	-	Fault zone in rhyolite-andesite tuffs.

99.8 - 101.3	-	Q F P crystal tuff - silicified, 1-3% py
101.3 - 118.2	-	Intermediate to felsic tuffs moderate chorite, sericite, 1-2% py
118.2 - 123.2	-	Feldspar-phyric dike/crystal tuff, silicified, 2-3% py
123.2 - 145.4	-	Q F P crystal/lithic tuff - moderately sericitic, tr-2% py.

145.4 EOH

MTS-40

Hole MTS-40 tested the "Southern Horizon" 1000 meters to the west of MTS-39. The argillite - QP crystal tuff sequence characteristic of the Southern Horizon was intersected but no economic sulphides were present.

Summary Log

0 - 7.6	-	overburden
7.6 - 14.4	-	Andesitic crystal tuff, weakly chloritic
14.4 - 23.4	-	Feldspar-phyric crystal tuff, weakly sericitic, 1-3% py.
23.4 - 32.6	-	Andesitic crystal tuff, weakly chloritic.
32.6 - 47.2	-	Felsic tuff with siliceous fragments, 1-5% py
37.2 - 81.9	-	Andesitic tuff/lapilli tuff.
81.9 - 87.4	-	QFP crystal tuff, weakly sericitic
87.4 - 119.8	-	Andesitic crystal tuff
119.8 - 154.2	-	Felsic crystal tuff/tuff, moderately sericitic, tr py.
154.2 - 158.4	-	Argillite/cherty argillite, 2-5% py
158.4 - 172.8	-	QP crystal tuff, tr py
172.8 - 188.1	-	Intermediate tuff, weak sericite/chlorite, tr py

188.1 EOH

MTS-41

Hole MTS-41 was drilled in the Mona shaft area to evaluate the down-dip extent of zinc stringer mineralization intersected in hole MTS-27. MTS-41 was almost entirely in diorite except for a thin sliver of silicified felsic ash. No economic mineralization was encountered.

Summary Log

0 - 7.3	-	overburden
7.3 - 113.9	-	Diorite with mafic dikes, pervasive carbonate
113.9 - 122.85	-	silicified Ash - blocky
122.85 - 147.6	-	Diorite - feldspar-phyric
147.6 - 160.3	-	F(Q)P dike
160.3 - 178.9	-	Diorite
178.9 EOH		

MTS-42

Hole MTS-42 tested the new "Southern Horizon" which is thought to correlate with the Lenora mine sequence. A thin cherty argillite and underlying QFP crystal tuff were intersected. However, there are no zones with significant sulphide contents.

Summary Log

0 - 9.4	-	overburden
9.4 - 43.4	-	Intermediate tuff/crystal tuffs, weakly sericitic, tr py
43.4 - 53.7	-	Diorite, feldspar-phyric
53.7 - 82.6	-	Andesite breccia/lapilli tuff, weakly chloritic, tr py 77.8 - 82.6 - minor chert
82.6 - 108.3	-	Diorite, feldspar-phyric
108.3 - 121.0	-	Andesite tuff
121.0 - 122.8	-	rhyolite tuff and cherty argillite, 1-2% py
122.8 - 158.6	-	QFP crystal tuff, moderately sericitic, tr py
158.6 - 186.3	-	Felsic cherty tuff, 1-2% py
186.3 - 191.1	-	Diorite
191.1 EOH		

MTS-43

Hole MTS-43 which is located 250 meters west of MTS-38 also tested the

extent of zinc mineralization in the Mona shaft area. A fine-grained, pyritic volcaniclastic with anomalous copper (255 ppm) and barium contents (1327 ppm) was intersected. This horizon can be correlated with a pyritic ash intersected in hole MTS-38 which is believed to be exhalative. Chalcopyrite-pyrite stringers were noted stratigraphically above and below the MTS-43 horizon. Additional follow-up drilling is warranted in the Mona area.

Summary Log

0 - 1.8	-	overburden
1.8 - 34.5	-	Diorite
34.5 - 75.0	-	Felsic Ash Tuff
		58.7 - 75.0 - moderately sericitic
		61.8 - 63.8 - 10-15% py, 1-2% cp as stringers (0.23% Cu over 2.0m)
75.0 - 79.3	-	Pyritic Volcaniclastic - 10-15% cherty fragments and light grey felsic ash; 5-7% v.fgr. pyrite (255 ppm Cu, 17 ppm Zn, 1327 ppm Ba over 4.3m).
79.3 - 131.4	-	Feldspar-phyric Crystal Tuff/Ash - patchy sericite
		130.5 - 131.1 - 25% py, 5% cp as stringer (1.29% Cu, 10.4 g/T Ag, 0.18 g/T Au over 0.6m)
131.4 - 143.35	-	Fortuna Fault gouge
		133.4 - 134.2 25% py, tr-1% cp as stringers (0.67% Cu over 0.8m).
143.35 - 152.4	-	Andesite crystal tuff - weak chl-ep; 1% py
152.4 - 174.2	-	Felsic to Intermediate Ash - weak sericite
174.2 - 179.65	-	Diorite - feldspar-phyric
179.65 - 184.7	-	Felsic Ash/Crystal Tuff - weak sericite
184.7 EOH		

MTS-44

Hole MTS-44 was drilled to test the exent of stringer mineralization in MTS-29. Although felsic tuffs of the central panel were intersected in the upper part of the hole, the target area was cut off by a thick diorite dike.p

Summary Log

0 - 4.9	-	overburden
4.9 - 51.0	-	Felsic crystal tuff/tuff
		4.88-32.2 - 1-5% py
51.0 - 51.6	-	Chert, tr py
51.6 - 66.3	-	Felsic tuff, patchy sericite, tr-1% py
66.3 - 76.0	-	Andesitic tuff with minor chert
76.0 - 80.6	-	Chert
80.6 - 96.6	-	Diorite, feldspar-phyric
96.6 EOH		

5. Conclusions

No zones of significant mineralization were encountered during the spring drill program but the drilling did enhance our understanding of the geology and structure of the Mt. Sicker area. Holes CM-1 to CM-6 were drilled on the west side of the Chemainus River on the Canamera Option. Holes CM-4, 5 and 6 intersected variable thicknesses of argillite which is correlated with the Lenora-Tyee horizon. Additional drilling is warranted around CM-5 which is close to Canamera hole 85-3 where zinc stringer mineralization was intersected. Hole CM-1 intersected a 7.7 meter wide zone of pyrite stringers with low metal values. CM-2 and 3 gave a section through the stratigraphy on the western edge of the property. Both holes encountered primarily andesitic material with only minor felsic interbeds. This is quite distinct from Abermin's Coronation zone where the mineralization is hosted in felsic, quartz-eyed crystal tuffs. A northeasterly trending fault may have offset the Coronation host rocks but the direction of movement along this structure is unknown due to the lack of a distinctive marker horizon.

Drilling on Mt. Sicker tested a variety of geological, geophysical and geochemical targets. Hole MTS-33 was drilled to test the Myra-Nitinat contact. The target was never reached as the hole stayed almost entirely within andesitic crystal tuffs of the Myra-Nitinat transition zone. Moderate core angles for bedding suggest that MTS-33 was drilled down the dip plane of the statigraphy. Thus the hole was collared on the north side of the Mt.

Sicker anticline. Holes MTS-35, 37 and 44 tested the extent of stringer type mineralization within the central panel of felsic volcanics. The only zone of significant mineralization was found in hole MTS-37 where a 22.8 meter wide zone assayed 400ppm Cu. Diorite dikes in the other 2 holes dilated the target areas. Holes MTS-39, MTS-40 and MTS-42 tested the new "Southern Horizon" which is thought to correlate with the Lenora-Tyee horizon. The argillite, quartz eye crystal tuff package which was intersected is similar to the package seen in holes CM-4, 5 and 6. Thus this southern argillite zone has been exposed for a strike length of 2.4 km. However, to date there are no economic sulphides associated with the zone. Holes MTS-38, MTS-41 and MTS-43 were drilled in the Mona shaft area located 1.2 km east of the Lenora shaft. A pyritic ash which was intersected in MTS-38 and MTS-43 has anomalous copper (288 ppm) and barium (1500 ppm) contents. This zone is thought to be exhalative in origin and as such warrants additional drilling. The target area was diked out in MTS-41.

Statement of Qualifications

I, Gary S. Wells, hereby certify that:

1. I hold an Honours Bachelor of Science degree in combined geology and chemistry (1975) from Carleton University, Ottawa, Ontario and a Ph.D degree in geology (1980) from Queen's University, Kingston, Ontario.

2. I am an associate member of the Geological Association of Canada and a member of the Canadian Institute of Mining and Metallurgy.

3. I have practised my profession in exploration continuously since graduation in 1980.

4. I have based conclusions contained in this report on knowledge of the area, my previous experience and results of field work conducted on the property.

Date: September 11, 1987

Gary Wells

Gary S. Wells, Ph.D.
Vancouver, British Columbia

Statement of Qualifications of Field Personnel

Michael J. Gray : B.Sc (Geology) 1985, University of British Columbia.

2 years full-time experience in mineral exploration

4 years part-time experience in mineral exploration

Address: c/o Minnova Inc., 4th Floor, 311 Water Street
Vancouver, B. C. (phone 681-3771)

0.00 TO 4.90	OVERBURDEN					casing
4.90 TO 44.95	DIORITE	Colour - green Grain size - cgr. with f-mgr phases massive with good intergranular texture f-mgr. dark green, massive to weakly foliated zones = phases of diorite or mafic dikes, carb-rich at: 11.7-12.55 19.8-20.6 27.0-28.1 30.9-31.6 34.45-34.7 35.85-36.15 40.2-44.95 - diorite becoming f.gr., weakly foliated; 1-2% white fsp crystals lower contact sharp	80 70	1% qtz-epidote veins - pervasive weak to moderate leucoxene	tr py in veinlets.	
44.95 TO 52.25	CHERT/ SILICIFIED ASH	Colour - light grey Grain size - very fine massive to weakly foliated - minor ash component 48.0m 50.5-51.3 - f.gr., green, feldspar-phyric intermediate dike (1% f's) - chilled contacts. 50.5m: contact	45 35	primarily silica-rich with wisps of sericite and chlorite = minor ash component.	tr diss py + cp - also occur in veinlets.	chemistry suggests felsic ash SiO2 = 72% - too low for chert
52.25 TO 74.95	FELSIC ASH with CHERT FRAGMENTS and BEDS	Colour - light grey Grain size - fine ashy parts foliated have 1-2% qtz phenocrysts in ash - chert interlayered with ash - locally have 5% mm sized white fsp(?) crystals 61.5m: foliation f.gr., green, intermediate dikes at: 62.5-63.1 65.9-66.2 66.3-66.7	50 45 80	ash - weakly to moderately sericitic	52.25-58.8: tr-1% py as disseminations and veinlets. 58.8-74.95: 1-2% py occurring primarily in veinlets parallel to foliation; also found in crosscutting veins. - also have tr. cp. - locally have more sulphides: 68.75-70.1: 2-3% py, tr cp - sulphides primarily in veinlets parallel to foliation 73.1-74.1: 10% py, tr cp in veinlets	

FROM TO	ROCK TYPE	TEXTURE AND STRUCTURE	ANGLE TO CA	ALTERATION	MINERALISATION	REMARKS
		68.8m: foliation	60			
74.95 TO 80.40	QTZ-PHYRIC CRYSTAL TUFF	Colour - grey Grain size - fine-med. 5-10% qtz eyes in v.fgr. ashy matrix. blocky core & fault gouge at upper contact. 76.5-76.65: fgr. green mafic dike	 50	moderately sericitic & weakly chloritic	tr-1% diss py	
80.40 TO 81.90	PYRITIC ASH	Colour - dark grey Grain size - very fine well-bedded qtz-phyric fragment at: 80.55-80.7 bedding 80.8 have pyritic matrix to chert and qtz-phyric fragments at: 81.0-81.1 81.25-81.9 lower contact = fault gouge	 70		20-25% v.fgr. pyrite	- looks like a very nice horizon - no visible sph or cp but sulphides are v.fgr - feels heavy - possibly baritic (very soft)
81.90 TO 156.60	FELSIC to INTERMED. ASH	Colour - greenish grey Grain size - fine foliated 1-2% qtz eyes 92.0m: foliation cherty looking interbeds at: 81.9- approx. 86.9 98.8-155.6 - unit looks more felsic - minor silicified/cherty zones interlayered with ash. fgr.-mgr., green diorite dikes carb-rich at: 113.5-113.75 118.7-118.9 119.2-119.9 120.3m	 60 40 65	weakly chloritic throughout 98.8-121.8: unit moderately sericitic 121.8-131.4: weak chlorite-sericite alteration	tr-1% py as disseminations and in veinlets 113.9-131.4: 1-2% py, tr cp - occur as crosscutting stringer. 131.1-131.4: 10-15% py as cross-cutting stringers	- looks similar to unit at 74.95-80.4 but fewer qtz eyes fault gouge + blocky core at 83.8-86.9 96.0-97.0 98.5-98.8 104.4-105.7 fault gouge at: 116.95-117.1

FROM TO	ROCK TYPE	TEXTURE AND STRUCTURE	ANGLE TO CA	ALTERATION	MINERALISATION	REMARKS
		137.0m f.gr light green intermediate dikes at: 139.05-139.2 139.4-140.0	60	131.4-156.6 - intense pervasive sericite with silicified patches	131.4-156.6: tr py as disseminations + thin (<1-2mm) veinlets. 148.7-151.7: 2-3% py, tr cp as cross-cutting veinlets	
156.60 TO 179.40	INTERMED. ASH TUFF	Colour - greenish grey Grain size - fine weakly foliated 1-2% small (<1mm) fsp crystals - locally have siliceous cherty beds bedding very indistinct + contact with overlying Felsic Tuffs - gradational 164.0m	 50	weak chlorite + very weak, patchy sericite	tr py as disseminations and veinlets	
179.40 TO 182.10	MAFIC DIKE (?)	Colour - green Grain size - fine well-foliated 180.0m	 30	3-5% carb veinlets	none	
182.10 TO 224.30	INTERMED. CRYSTAL TUFF/ASH E.O.H.	Colour - greenish grey Grain size - fine weakly foliated - have fsp-phyric (10-15%) and qtz-phyric beds (15%) interlayered within a predominantly ashy matrix. 184.5m 203.0m 210.0m fault gouge at: 220.0-220.4	 40 45 45	weakly chloritic with patchy silicified areas.	tr-1% py - primarily as disseminations with the odd stringer. py in stringers occur as subrounded cubes up to 0.5cm in diameter. 209.1-224.3: 1-2% py as diss + stringers 219.85-220.1: 5-10% py, 1% cp in q.v.	chemistry indicates unit to be more felsic in composition (SiO2 = 72.06%)

LEGEND

CRETACEOUS

- 4 — Nanaimo Group Sediments
- 3 — Diorite Intrusions(age unknown)

PALEOZOIC
SICKER GROUP

- 2 — Rhyolitic-Dacitic Volcanics
- 1 — Andesitic Volcanics
- ▬▬ — Mineralized chert, ash argillite (mine package)

SYMBOLS

- Shaft/old workings
- Bedding
- Anticline
- Syncline
- Fording Coal Lease South Boundary
- ○MTS40 — Drill hole collar location
