#### INTRODUCTION

This report summarizes exploration activities in the Furry Creek area of the Britannia property during the 1987 field season.

The Furry Creek valley and the Clipper Creek valley contain the strike continuation of the Britannia Mine sequence which hosts the former Britannia orebodies. Some 55 million tons of copper ore was mined from the Britannia Mine, including a massive portion of 2.1 million tons grading 1.5% Cu, 4.4% Zn, 0.3 oz/T Ag and 0.28 oz/T Au.

In 1986, a drill program at the Watershed prospect intersected two zinc-rich exhalitive horizons occuring in pyroclastic rocks stratigraphically above a composite dacite flow/dome. Quartzchalcopyrite stringer mineralization and attendant chlorite/sericite alteration appeared to intensify toward the east. (Burge, 1986)

In 1987, mapping and lithogeochemistry traced the mineralized package to a cliff face some 400 metres further east. There spectacular chalcopyrite-pyrite and sphalerite stringers were discovered within the dacite flow/dome. Mapping 400 metres further east located cherty ash beds with 3-4% disseminated chalcopyrite immediately above a silica-flooded andesite. This andesitic unit is remarkably similar to the "silica-healed breccia" as described by Hodgson (1969) as the host for the No. 8 orebody, the massive portion at the Britannia Mine.

These exciting targets were slated to be drilled in the fall of 1987, but the inability to obtain a machine capable of drilling in the rugged, precipitous terrain forced the program to be delayed until 1988.

#### LOCATION, ACCESS, PHYSIOGRAPHY

The Furry Creek project area is located 40 kilometres north of Vancouver on Highway 99 (Figure 1). Access to the western extent of Minnova Inc.'s Furry Creek grid is by an eight kilometre rough four-wheel drive road which leaves Highway 99 five kilometres south of Britannia Beach. The Furry - Clipper divide area can also be accessed by 40 km of good condition road north through the Greater Vancouver Watershed, leaving from the Seymour Demonstration Forest.

The Furry - Clipper divide area represents the saddle between Furry Creek draining west toward Howe Sound and Clipper Creek, which joins Seymour River in the east. The Clipper Creek valley is a rugged, steep-walled, east-west trending valley with original growth douglas fir.

#### PROPERTY STATUS

The Furry - Clipper divide area is in the western portion of the Britannia property, which consists of 310 crown granted claims, 6 reverted crown granted claims, and 5 staked claims totalling 8,175 hectares. Anaconda Canada purchased the property from Britannia Mining and Smelting Co. in 1962, and Minnova Incorporated (formerly Corporation Falconbridge Copper) optioned the property from Anaconda in June 1984. Fleck Resources Ltd. acquired Anaconda's interest in late 1985.

#### FIELD METHODS

Detailed 1:1000 scale contour maps were used as base maps combined with slope-corrected gridlines for control purposes.

#### GEOLOGY

#### Regional Geology

The Britannia property is underlain by lower Cretaceous metavolcanic/sedimentary rocks of the Britannia pendant, one of the many volcano-sedimentary "belts" within the Coast Plutonic Complex (Figure 2).

#### Geology of the Furry Creek Area

The Furry Creek valley contains a complicated interbedded succession of andesitic - dacitic pyroclastic rocks which comprise the "Mine Sequence," which hosts the former Britannia VMS deposits to the west. Pyroclastic rocks of the Mine Sequence conformably overlie the Britannia Ridge dacite dome-intrusion and generally strike NW-SE. Units dip 30° south on the north valley wall and increase to 70° to 80° south at the bottom of the valley.

The volcanic units in the valley floor along the course of Furry Creek are typically strongly sericitized and chloritized. In areas of intense alteration, these units have a well developed schistosity, and have been grouped within the "Britannia shear zone." The "Britannia shear zone" is a discordant zone of alteration which hosts the VMS deposits at Britannia and numerous small prospects such as the Robinson, Furry and Fairwest prospects in the Furry Creek valley. This shear/alteration zone has been traced eastwards to the Watershed Prospect, the focus of our 1986 program. (Gibson, 1984)

A 900 metre drill program at the Watershed Prospect at the head of Furry Creek intersected a complex succession of intercalated dacitic pyroclastic and rhyolite to dacite flows. The Watershed stratigraphy was interpreted to be a felsic vent area based on the observed thickening of the massive lower dacite dome, a quartz feldspar porphyritic unit (thin section evidence) which displays hyaloclastite textures and is locally flow banded.

#### Geology of the Furry Creek Area (continued)

The four holes were drilled to test coincident VLF and DEEP-EM responses occuring in the area of outcrops of quartzchalcopyrite-pyrite mineralization. The following is a list of stratigraphy encountered:

- 1. Andesite
- 2. Upper Dacite flow
- 3. Dacite Tuff-breccia
- 4. Dacitic Ashes, lapilli tuff
- 5. Lower Dacite flow (Q.F.P.)
- 6. Lower Contact Ashes

Two zinc-rich siliceous exhalitive were hosted by dacite ashes situated above the lower Dacite flow. (Burge, 1986)

The summer mapping program continued toward the east into the Clipper Creek valley, where cliff faces on line 4 + 00 E expose the Watershed sequence intersected in the 1986 drill program.

#### Geology of the Furry - Clipper Divide

The purpose of the 1987 mapping program was to map out units encountered during drilling at the Watershed. Spectacular mineralization was located within this stratigraphy exposed in creek beds, cliff faces, and old workings 400 metres to the east (L4E).

The majority of rock types outcropping are andesite to dacite volcanics with minor intercalations of argillite and chert first appearing around L6East and continuing toward the east (see Figure 4). The lowermost unit exposed in the valley floor is an andesitic to dacitic, heterolithic, lapilli tuff which contains numerous flame-like clots interpreted to be collapse pumice lapilli. Sulphide fragments occur within this unit. Stratigraphically above this unit a more competent felsic unit occurs as a emerald green, moderately foliated, homogeneous aphyric to quartz feldspar phyric rock. This unit is thought to be the stratigraphic equivalent of the Watershed Lower Dacite flow/dome. A complex succession of lapilli tuffs and fine grain dacitic ashes occur above this unit, which frequently contain disseminated chalcopyrite, pyrite and sphalerite mineralization. A coarse tuff-breccia unit is situated above these lapilli tuff/ashes and forms the immediate hanging wall unit to the mineralized rocks. The uppermost unit in the L4E area is a massive, homogeneous dacitic flow.

Geology of the Furry - Clipper Divide (continued)

The eastern part of the project area (L8E to L10E) contains a package of rocks which is interpreted to be stratigraphically below the L4East units. The lowest and most unusual member is an andesite unit which has been shattered into fragments and flooded with silica. The andesitic fragments contain 1 - 5% disseminated pyrite, and in some specimens, amygdules were recognized, suggesting this unit may have originally been a flow. The matrix silica content ranges from 5 to 50%. Structurally (and presumably stratigraphically) above this unit, a sequence of interbedded cherty argillites, rhyolite ashes and andesite to dacite lapilli tuffs, crystal tuffs and ashes were encountered. These units have been interpreted to represent a transitional sequence between dacitic and andesitic volcanism.

Structurally, the Furry - Clipper Divide sequence forms an anticline-syncline pair based on strike and dip information obtained in the field (see Figure 5). A moderate to intense foliation has been developed, especially affecting the pyroclastic rocks, and the degree of foliation is dependant on the degree of alteration.

All rocks have been classified according to Fisher, 1966 (Figure 3).

#### MINERALIZATION AND ALTERATION

A number of showings of massive pyrite and massive chalopyrite stringers occur hosted within the lower dacite flow/dome, a massive, homogenous unit. Extensive chlorite and sericite development accompanies these showings. Pyrite veins measuring up to 1 metre wide were found in the 4 + 70 E, 0 + 60 S area. Massive chalcopyrite stringers located 4 + 50 E, 0 + 70 S and 8 + 20 E, 0 + 80 N measured up to 5 cm and were accompanied by strong chlorite alteration. Chalcopyrite, sphalerite mineralization was also located within the lowermost silica-flooded andesite, notably at 8 + 70 E and 0 + 60 S, where the footwall silicaflooded andesite shows considerable barium enrichment (up to 5310 ppm).

Stratigraphically above this unit and striking between 0 + 50 S, 7 + 50 E and 1 + 00 S, 9 + 00 E is a zone of highly anomalous zinc values (up to 1.9% Zn). These anomalous values occur within transition rocks, and represent a significant target in 1988.

The Furry - Clipper divide has a soda depletion zone measuring  $650 \times 300$  metres to where traverses ended on line 10 + 00 E. This alteration is discordent, and affects several different rock types.

#### CONCLUSIONS

Extensive chalcopyrite, pyrite and sphalerite stringer mineralization are considered to be those which accompany volcanogenic massive sulphide deposits. A large hydrothermal system was active within the rocks of the Furry - Clipper divide, as is evident by the large area of soda depletion and potassium enrichment combined with widespread quartz veining. The occurance of chert and argillite units occuring in the L 8 + 00 E to L 9 + 00 E are the first sedimentary units encountered east of These sediments represent excellent drill the Watershed. targets, as they occur at a major lithologic contact. The presence of argillite lends support to the concept that these rocks have been deposited in a subaquous environment. Values of up to 1.1% Cu and 1.9% Zn were obtained in these cherty ashbeds, and mapping showed this horizon to be stratigraphically above a silica flooded andesite breccia. This unit is remarkably similar to the "silica healed breccia" as described by Hodgson (1969) as the host for the No. 8 orebody in the prolific Britannia mine 5 kilometres to the west.

#### RECOMMENDATIONS

- 1. A helicopter-supported drill program to test geological/geochemical targets generated in 1987.
- 2. Extend geological mapping and sampling from L 10 E to L 26 E
- 3. VLF, Mag, and IP surveys should be performed over the remainder of the grid.

Drill test targets generated by geophysical surveys.

4. Locate, investigate and assess Bank of Vancouver, Sun, Belle, and Bulliondale prospects.

WORK DONE IN 1987

#### APPENDIX 1

SUMMARY OF WORK DONE - 1987 PROGRAM

Linecutting: 16 kilometres of line was added to the existing Furry Creek grid.

Geology: 12 kilometers of 1:1000 scale grid mapping was completed in rugged terrain.

Geochemistry: Approximately 135 rock samples and 10 assay samples were collected in the Furry - Clipper Divide Area.

Site Preparation:

2

One drill set-up was constructed in rugged terrain for the 1988 program.
