---------	---	--------

The Oka property consists of 13 mineral claims (185 units) in the Osoyoos and Similkameen Mining Divisions, located 12 km northwest of Peachland, B.C. Eleven of the claims were staked on behalf of Fairfield Minerals Ltd. by Cordilleran Engineering during March, 1986; the remaining two claims were purchased.

Access to the property is excellent via the Brenda Mine road and the Headwaters Road; the latter bisects the claims from east to west. Pine, balsam and fir forests cover the property.

The claims are underlain by Cretaceous granodiorite which intruded Upper Triassic Nicola Group volcanics, clastic sediments and limestone. Carbonate horizons were variably altered to marble and skarn, which locally contain pods of massive sphalerite, chalcopryite, pyrite and pyrrhotite with scattered gold values. Disseminated chalcopryite, sphalerite and molybdenite have been found in the intrusive on the west end of the property. Previous exploration efforts concentrated on the massive sulphide zones and potential porphyry deposits.

Exploration programs in 1986 and 1987 were conducted by Cordilleran for Fairfield.

The 1986 program, which focussed on gold, consisted of linecutting, soil sampling, prospecting and reconnaissance mapping. A number of large gold soil geochemical anomalies were defined; prospecting of some of these revealed that the higher gold values were associated with disseminated and massive sulphides in skarn. Known gold-bearing areas were highlighted by soil geochemical anomalies.

In 1987 a program of detailed grid soil sampling, magnetometer surveying and extensive trenching further tested areas of anomalous gold soil geochemistry.

This report covers only the results of three detailed soil grids which are located on the Oka 1, 2 and 5 claims. The purpose of the soil grids was to define and close off gold soil anomalies that had been partially outlined by the 1986 work.

It is concluded that most of the gold soil anomalies in the three subject areas have been delineated by the 1987 work. Possible sources of gold anomalies in two of the areas may be auriferous skarn or massive sulphide zones. Anomalous values in the third area cannot be explained by the present data.

## 2.0

## RECOMMENDATIONS

The following program is recommended to further define the known targets and determine more precisely the lithologic association and extent of the gold mineralization within two of the three subject areas.

1. In the Garnet and South Cap grid areas, collect additional soil samples on 25 m x 25 m grids around anomalous stations defined in 1987, and analyse for gold.
2. In the Garnet and South Cap grid areas, carry out detailed prospecting to locate mineralized bedrock sources of the gold soil geochemical anomalies.

No further work is recommended in the Peachland Creek grid area.

Respectfully submitted

*B. K. Bowen*

## 3.0

## I N T R O D U C T I O N

3.1 LOCATION AND ACCESS

The Oka property is situated in the Okanagan area of B.C. (Figure 1). The junction of the Headwaters Road (Figure 2) which provides access through the center of the claim block, and the paved Brenda Mine road is 11 km from Peachland.

The claims are on the east edge of the Trepanege Plateau, between elevations of 900 m and 1500 m. Forest cover of pine, balsam and fir is extensive. The property is traversed from west to east by Greata Creek and from northwest to southeast by Peachland Creek.

3.2 CLAIM DATA

The status of the Oka, Iron Horse and Cap claims is indicated in Table 1, and their locations are shown on Figure 2. The Oka 1-11 claims were staked in March, 1986, by Cordilleran Engineering for Fairfield Minerals Ltd. The Iron Horse and Cap claims were purchased by Fairfield Minerals from the claim holders.

Group 1 claims dealt with in this report include the Oka 1-5, Cap and Iron Horse claims.

### 3.3 HISTORY

The earliest reported work within the area of the Oka claims was in 1898/99 on the Silver King and Alma Mater properties at the west end of the present claim block. Three shallow shafts (to 4.3 m) and one deep one (76 m) were sunk and four adits (to 70 m) and one crosscut (58 m) were driven in intrusive rocks. The target was "free milling" gold. In more recent years this area has been mapped (1965), soil sampled (1967) and diamond drilled (4 holes, 1979). A porphyry copper/molybdenum deposit was the objective of the later work.

The Iron Horse claim, near the center of the present property, has been another focus of activity which started in the 1930's. The area has been variably mapped, trenched, sampled and geophysically surveyed; an unknown number of holes were drilled in 1956.

A third area to receive previous work is now covered by the Cap and Oka 4 claims, north of the junction of the Brenda and Headwater roads. Exploration activity included mapping, trenching, diamond drilling (? holes, 1965), soil sampling and a magnetometer survey. Skarn-hosted Cu-Zn massive sulphides were the targets on the Iron Horse and Cap claims.

Other areas of the present property were variously prospected, soil sampled and geophysically surveyed during the late 1960's and early 1970's.

Current work has focussed on gold. In 1986, a program of linecutting, soil sampling, prospecting and reconnaissance mapping was carried out. A number of large gold soil geochemical anomalies were defined; prospecting of some of these revealed that the higher gold values are associated with skarn and massive sulphide zones.

### 3.4 1987 EXPLORATION PROGRAM

The 1987 program consisted of detailed grid soil sampling, a magnetometer survey over the Iron Horse claim and about 3,000 linear metres of trenching which tested areas of anomalous gold soil geochemistry in several widely separated areas.

This report covers only the results of three detailed soil grids which are located on the Oka 1, 2 and 5 claims. The work was carried out and supervised by geologists T. Macdonald and B. Bowen respectively.

Purpose of the above work was to define and close off gold soil anomalies that had been partially outlined in the 1986 work.

## 4.0

## G E O L O G Y

4.1 REGIONAL GEOLOGY

The Oka property is situated in the northwest corner of GSC Map 15-1961, Kettle River, mapped by Dr. H. W. Little, 1958-59 (Figure 3). The property is underlain by pendants of sedimentary and volcanic rocks of the Upper Triassic Nicola Group which are cut by Cretaceous(?) age Nelson plutonic rocks. East of the property both intrusive and Nicola group rocks are covered by large areas of Eocene/Oligocene volcanic flows.

4.2 PROPERTY GEOLOGY AND MINERALIZATION

In order to facilitate the discussion of geochemical results in Section 5.2 a brief summary of the property geology and mineralization is given below. Outcrop distribution and geological units within the east half of the property are presented on Plate 1. For the reference source which provides a more complete description of property geology and mineralization, see Section 6.0.

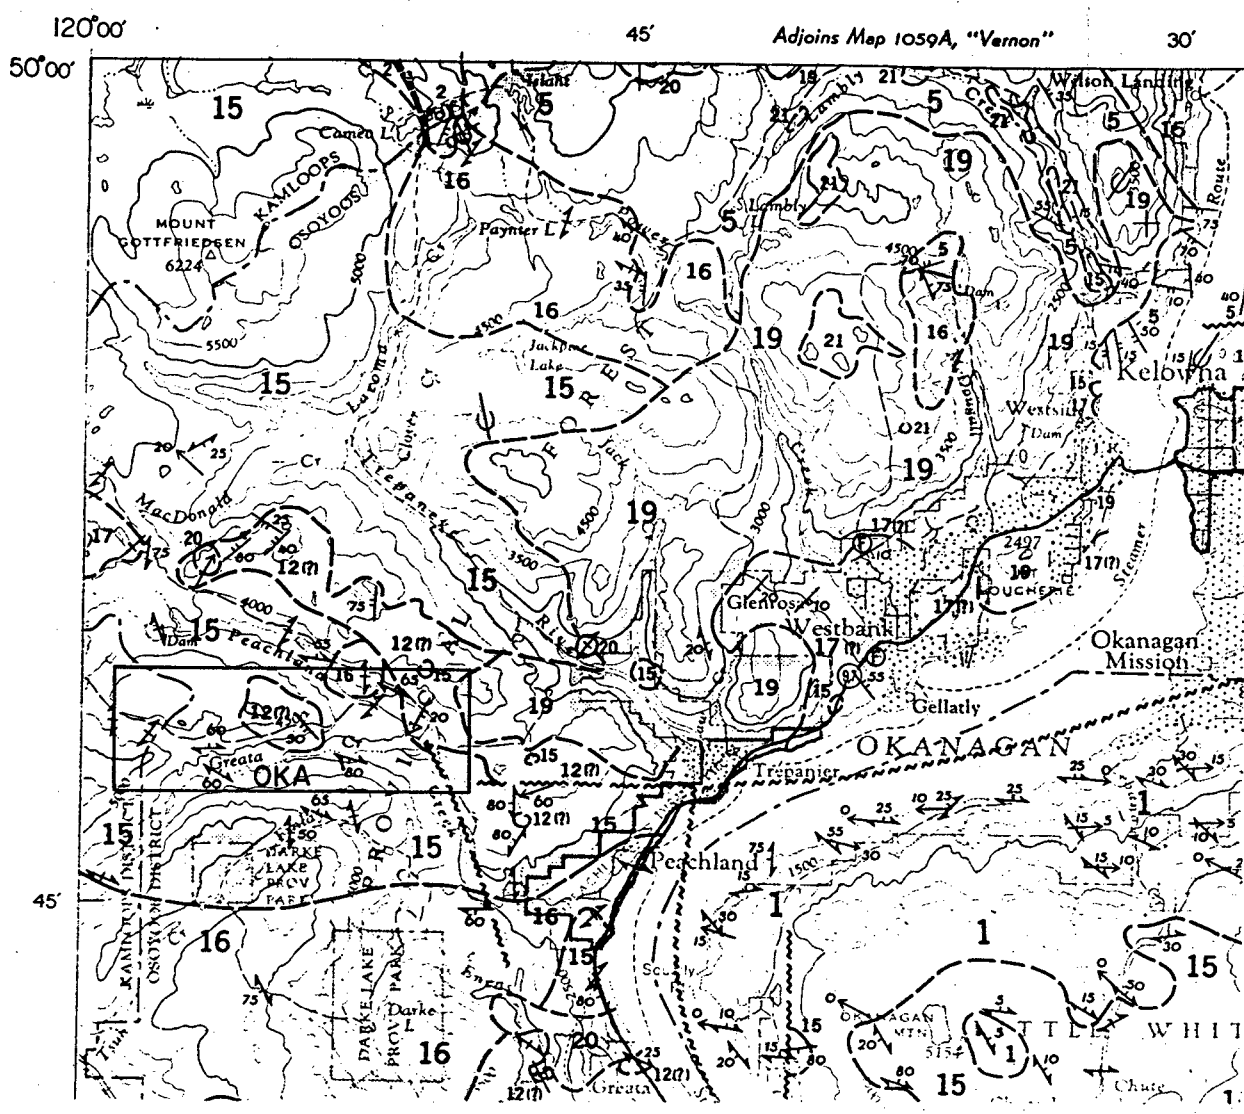

Upper Triassic Nicola Group rocks include limestone, clastic sediments and intermediate to basic volcanic rocks. Carbonate horizons were variably altered to marble and skarn at or near intrusive contacts. Pendants of Nicola rocks underly the central and eastern parts of the property.

The southwest, southeast and north-central portions of the property are underlain by batholiths of probable Cretaceous age. The plutonic rocks are predominantly diorite to granodiorite in composition.

The Nicola Group and plutonic rocks are locally cut by later (Tertiary?) quartz feldspar porphyry and basalt dikes.

Gold mineralization occurs in several widely separated areas on the property. Significant gold values have been obtained from massive sulphide lenses (consisting mainly of pyrite and pyrrhotite with lesser amounts of arsenopyrite, chalcopyrite and sphalerite) located within or between skarn and marble units, from sulphide-poor garnetite skarn and from quartz-arsenopyrite veins. Fine visible gold has been identified within marble containing minor disseminated arsenopyrite.

In the southwest corner of the property a zone of intense sericite alteration is located within a granodiorite unit. The zone contains abundant fine quartz veins, coarse disseminated pyrite and local molybdenite and hematite. Chip samples across this zone returned interesting silver values, but no gold.

## G E O C H E M I S T R Y

5.1 INTRODUCTION

A total of 162 soil samples were collected on the three 1987 grid extensions which are the subject of this report. The totals per grid area are as follows:

<u>Grid Area</u>	<u>Claim(s)</u>	<u>Number of Samples</u>
Garnet	Oka 1 & 2	42
Peachland Creek	Oka 1	45
South Cap	Oka 5	75

End points from the existing 1986 detailed (25m x 25m) grids provided control for 1987 grid extensions. Sample lines, oriented east-west, were established using compass and hip chain at 25 metre intervals, and samples were collected at 25 metre spacings on these lines.

All samples were collected from the "B" soil horizon and placed in kraft paper bags. Sample numbers consisting of grid coordinates were marked on each bag and on flagging at each sample site. The samples were sent to Acme Analytical Laboratories Ltd., Vancouver, where they were dried, screened and the -80 mesh fraction used for Au analyses. Each 10 gram sample was ignited at 600 degrees Celsius, digested with hot aqua regia, extracted by MIBK and analysed by graphite furnace atomic absorption. *10-30 cm depth*

5.2 RESULTS

The Au results for the above 1986 detailed grids and their 1987 grid extensions are plotted on Figures 4 to 6. Grid locations relative to outcrop distribution and geological units are shown on Plate 1.

Statistical analysis of the 1986 main (200m by 50m) grid results gave the following Au categories (in ppb):

Background	<5
Weakly Anomalous	5-19
Anomalous	20-65
Strongly Anomalous	>65

Discussion of results from the three 1987 detailed grid extensions are based on these statistics.

GEOCHEMISTRY - RESULTS Continued5.2.1 Garnet Grid

Two of the three small (25 to 50 m wide, 50 to 100 m long) anomalous areas partially delineated in 1986 were closed off by the 1987 work. The western-most anomaly, in the vicinity of 3250N/9200E, is still open to the south.

No outcrop has been mapped within the detailed grid area. Adjacent areas to the northwest and southeast are underlain by marble and skarn intruded by granodiorite to the east. The source of the Au soil anomalies may be skarn or massive sulphide hosted gold mineralization similar to occurrences at the nearby Iron Horse claim.

5.2.2 Peachland Creek Grid

This detailed grid area contains scattered single value anomalies up to 110 ppb Au. No anomalous patterns are present. The area is underlain by granodiorite. The anomalous values cannot be explained from the present data.

5.2.3. South Cap Grid

The three small (up to 30 m wide by 90 m long) anomalous areas partially delineated in 1986 were closed off by the 1987 work. A single value anomaly at 2725N/12950E remains open to the east.

The grid area is underlain by marble. Although no mineralization has been observed in outcrops mapped to date, localized auriferous massive sulphide zones may be present beneath overburden cover. Massive sulphide zones containing minor gold occur within marble at the nearby Cap showing.

STATEMENT OF QUALIFICATIONS

I, Brian K. Bowen, hereby certify that:

1. I am a consulting geologist resident at 12470 99A Avenue, Surrey, B.C. V3V 2R5, providing services to Cordilleran Engineering Ltd.
2. I am a graduate of the University of British Columbia (B.A.Sc., Geological Engineering, 1970).
3. I have been employed as both a mine and exploration geologist since 1970 in British Columbia and elsewhere.
4. The work described in this report was done under my direct supervision.
5. I am the author of this report and have assessed the results of the field work conducted on the Oka property during the period June 1 to 3, 1987.
6. I am a member in good standing of the Association of Professional Engineers of the Province of British Columbia.
7. I have no beneficial interest in the claims covered by this report or in Fairfield Minerals Ltd.

B. K. Bowen, P.Eng.

CAP AREA

SOUTH CAP GRID  
See Figure 6

**LITHOLOGY**

**TERTIARY**

- 4 Basalt; olive green dykes and flat-lying flows.
- 3 Quartz-Felspar Porphyry; dykes of granite(?) composition, which may be part of the Correll intrusion.

**CRETACEOUS(?)**

- 2 Granodiorite to Diorite; massive, medium to coarse grained with more mafic-rich border zones and local moderate to strong perthite alteration.

**UPPER TRIASSIC**

**NICOLA GROUP**

- 1a Skarn; massive, coarse grained, predominantly red-brown garnet with pyroxene and local minor epidote, calcite, magnetite and hematite. Light coloured, fine grained, bonded, calc-silicate hornfels is often interbedded. Skarn hosts local disseminated and massive sulphides.
- 1b Marble; light to dark grey, locally fossiliferous, poorly preserved bedding, strongly fractured with abundant white calcite veinlets.
- 1c Siltstone; block calcareous to siliceous (thin) with local chert sabbie conglomerate, heterolithic slump breccia and greywacke. Often interbedded with 1v and 1c.
- 1v Andesite to Basalt; dark green, massive to weakly flow banded, finely to coarsely crystalline with abundant feldspar and augite phenocrysts. Commonly strongly sheared and chlorite altered.

**LEGEND**

- Geological Contact, known, inferred
- Bedding with dip angle
- Outcrop; known, approximate
- Massive Sulphide skarn, predominantly pyrite and pyrrhotite with local arsenopyrite, chalcocopyrite, sphalerite and gold values
- Rock sample location and sample number
- Soil sample location and sample number
- 3000N Cut grid line
- OKA9/OKA7 Claim boundaries and LCP location
- Road, 4X4 Trail
- Adit
- Trench
- Pit, shaft

**Note:**  
Complete results for rock and soil samples appear in report appendix.

**GEOCHEMISTRY**

- 1986 detailed (25m X 25m) soil grid
- 1987 detailed (25m X 25m) soil grid

**GEOLOGICAL BRANCH ASSESSMENT REPORT**

**16,788**
