SET CLAIM GROUP

PART A

SUMMARY

The SET mineral claim group in the Greenwood Mining Division is located three km southwest of the Winnipeg - Golden Crown Mine, a former gold producer in the historic Phoenix-Boundary Mining Camp of central southern British Columbia, about 500 road km east of Vancouver. The property is conveniently accessible from Highway No. 3, an all weather two wheeled old mine-haulage road to the Phoenix Mine and Lexington Mine near the U.S.-Canada border, and the Lone Star Mine in Washington State.

The property is situated within the Paleo-Mesozoic volcano-sedimentary strata consisting mainly of bedded chert, greenstone, argillite, paragneissic rocks (schists) and argillite in order of abundance. These rocks are intruded by a granodiorite in the central north and northeast sector of the property. Lime silicate and/or skarn deposits are located along the limestone-granodiorite contact zone.

In the eastern sector of the property, a pyritized, limonitic, northerly striking steeply dipping quartz vein was intermittently explored by several trenches and shallow shafts over a total strike length of 120 m (Overlander Workings). The vein ranges in width from 0.2 to 0.45 m and cuts through an intensely altered cherty-argillite unit near an intrusive granodiorite stock.

Channel samples from the vein returned up to 0.590 oz Au/ton across 0.40 meters.

A geochemical survey completed over the property disclosed two correlative anomalous areas. One of the areas (A) occurs adjacent to and east of the Overlander Workings.

The VLF-EM survey delineated two strong east-west anomalies correlating with geochemical anomaly A.

The magnetometer survey disclosed a series of peripheral lows in the prime correlative area B.

CONCLUSIONS

The geochemical surveys were successful in delineating known areas of mineralization and other areas of potentially economic mineral zones. The VLF-EM survey results indicate that the preferred indicated structural direction is east-west. The two strong east-west-trending VLF-EM anomalies occur correlative to A and the area of the northerly-trending Overlander Workings suggest that the controlling mineral structures are east-west with complementary northwest (Overlander) structures.

RECOMMENDATIONS

Detailed geological, geochemical and I.P. surveys are recommended in the two designated anomalous areas to locate Overlander type or skarn associated gold-bearing zones.

Other localized geochem anomalous areas should be investigated and detailed if considered geologically encouraging to the localization of gold-bearing zones.

Respectfully submitted

Laurence Sookochoff, P.Eng

GEOCHEMICAL AND GEOPHYSICAL ASSESSMENT REPORT

for

OSSA RESOURCES LTD.

on the

SET CLAIM GROUP

PART B

INTRODUCTION

An exploration program consisting of geochemical and geophysical surveys was completed on the SET claim group of Ossa Resources Ltd. during October 1986. The program was a follow-up to former exploration which resulted in the location of a number of mineralized areas one of which is termed the Overlander Zone. This specific mineral zone is a structurally related quartz hosting gold-bearing sulphides northerly-trending zone with significant gold values.

The purpose of the 1986 exploration program was to delineate the zone, to locate potential parallel mineralized zones and to locate mineralized areas that may prove to be economic.

The information for this report was obtained from sources as cited under References, from exploration work the writer completed in the Boundary-Phoenix mining camp and from the supervision and management of the exploration program reported on herein.

PROPERTY

The property consists of three contiguously located mineral claims totalling 29 units, four located two post claims and one reverted crown grant. Particulars are as follows:

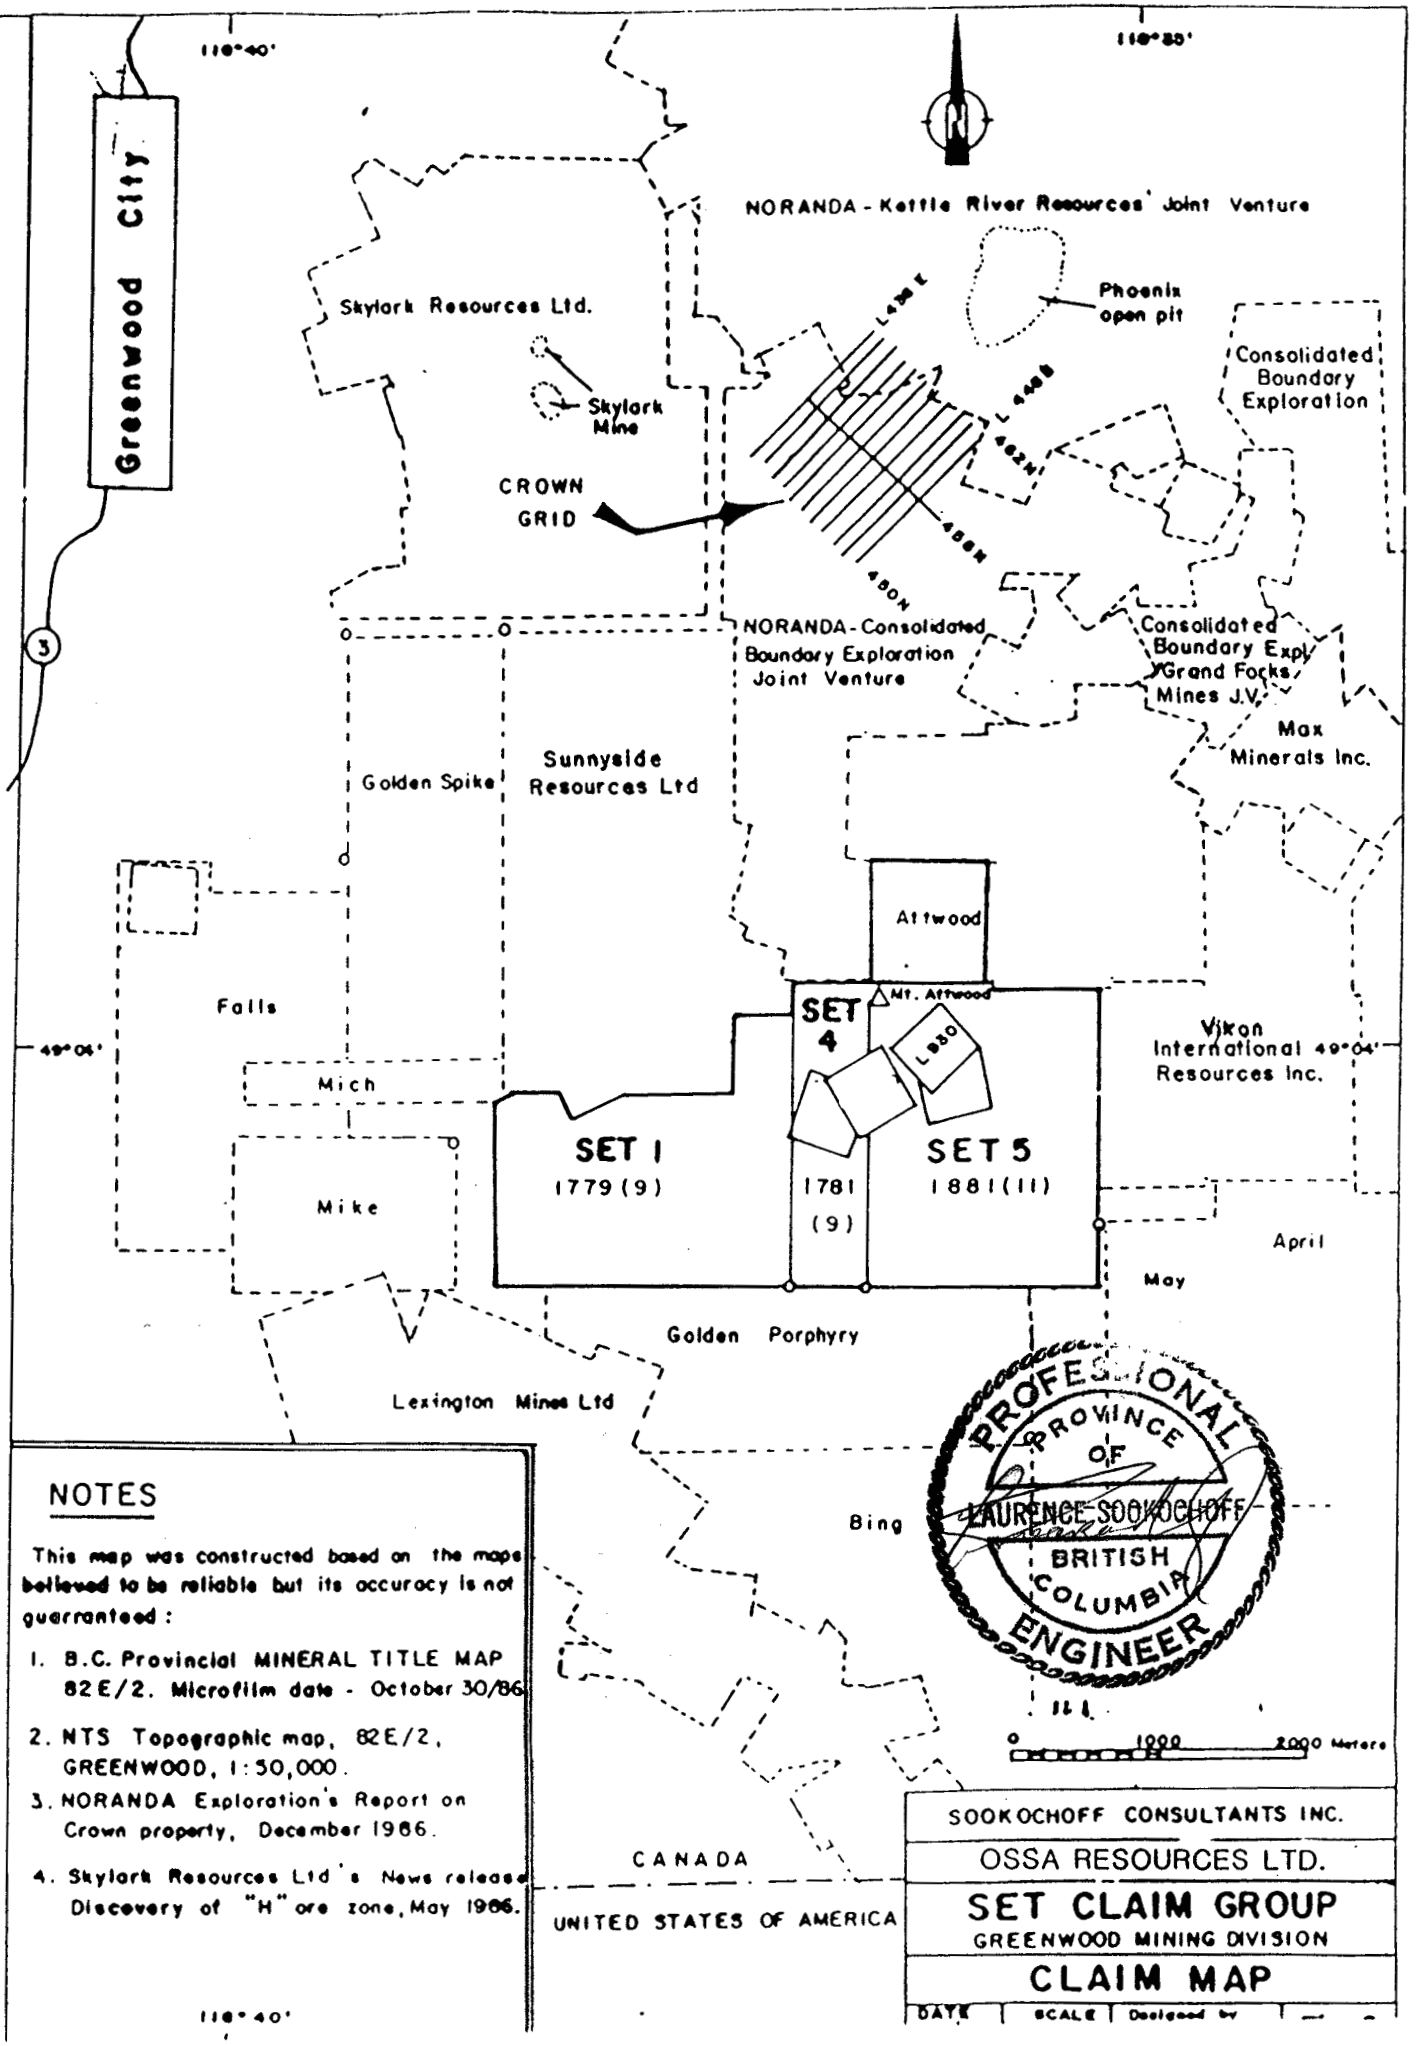
Claim Name	Units	Record No.	Expiry Date
SET 1	9	1779	Sept. 21, 1991
SET 4	4	1781	Sept. 21, 1991
SET 5	16	1881	Nov. 21, 1992
Attwood 1-4		4561-4564	Apr. 28, 1991
	Lot No.		
Lookout	930	2157	May 1, 1993

LOCATION AND ACCESS

The SET claim group is located within the historic Phoenix-Boundary Mining Camp in the Greenwood Mining Division. The general area is serviced by readily available paved roads and an all weather mine-haulage dirt road between the Phoenix Camp and the Lone Star Mine in Washington State. The center of the claim block is at 49 degrees 02 minutes N latitude and 118 degrees 37 minutes longitude.

Access to the property is conveniently provided by Highway No. 3 and an all weather mine-haulage road. Numerous logging roads and bulldozer trails criss-cross the entire property area.

A four-wheel drive vehicle would be required for access by secondary roads and trails at the higher elevations on the property.



NOTES

This map was constructed based on the maps believed to be reliable but its accuracy is not guarranteed :

1. B.C. Provincial MINERAL TITLE MAP 82E/2. Microfilm date - October 30/86.
2. NTS Topographic map, 82E/2, GREENWOOD, 1:50,000.
3. NORANDA Exploration's Report on Crown property, December 1986.
4. Skylark Resources Ltd's News release Discovery of "H" ore zone, May 1986.

GREENWOOD MINING DIVISION

CLAIM MAP

DATE | SCALE | Designed by

PHYSIOGRAPHY, CLIMATE, WATER AND POWER

The SET property covers a moderately dipping southward-facing slope of Mt. Attwood, 15 air km northwest of Grand Forks near the International border in south-central British Columbia. The two prominent topographic features on the property are the westerly-flowing McCarran and easterly-flowing May Creeks, divided at the central-south end of the property. A road paralleling the two Creeks marks the intervening valley between Mt. Attwood to the north and Mt. Wright to the south.

Relief on the property is 485 m from 1200 m elevation of the McCarran Creek on the southwest corner to the 1685 m at the Mt. Attwood summit to the north. The topography is generally moderate except for local rugged portions on the northern and northwestern sectors of the property. Topographic profile on the property for its entire north to south length ranges from 10 to 25 degrees. The steep slope on the northern part displays reasonable rock exposures, but the greater part of the south of the property is thickly vegetated with scarce outcrops. Vegetation consists of dry, open fir, cedar and pine forest with alpine meadows and low brushes.

The climate in generally mild with low summer precipitation and moderate winter snowfalls. Annual precipitation is approximately 30 cm. The regional tempertature ranges from -15 degrees to +40 degrees C. Fresh snow in the area occurs by mid-November and is snow free by the end of April.

Sufficient water for all phases of the exploration program would be available from McCarran and May Creeks and their numerous upstream tributaries.

A power line passes through the southern portion of the property with a gas pipeline within one km south of the property.

TRANSPORTATION AND SUPPLIES

A CPR rail line passes through Grand Forks 15 air km to the east. Castlegar, 90 km east of Grand Forks is serviced daily by commercial airlines. Most exploration supplies are obtainable at Grand Forks or Greenwood.

HISTORY

Adjacent Mines and Deposits

The history of prospecting and exploration in the Phoenix-Boundary Mining Camp dates back to the early 19th century. In 1891 large copper ore deposits were discovered at Deadwood and Phoenix camps, followed by construction of copper smelting plants at Boundary Falls, Greenwood and Grand Forks. The historic Phoenix mine, five km north of the SET property, produced a total of 30 million tons averaging 0.85% copper, 0.033 oz/ton gold, and 0.20 oz/ton silver during the initial production period from 1900 to 1919 and subsequently from 1957 to 1975.

The three major copper smelters mentioned above accepted any gold-silver-bearing ore from the surrounding areas for custom milling, and this enabled a swarm of small mining operations to exist in addition to the main copper mines at Phoenix, Deadwood, Motherlode, etc. This probably triggered numerous lode gold prospects in the area. The Winnipeg-Golden Crown, three km northeast of the SET was reportedly the largest former gold producer in the area.

Set Claim Group

The two contiguously located claims, SET 1 and SET 4, were reported to be staked initially by Mervin Boe, prospector, on September 5, 1979. The SET 4 claim overlaps two crown granted claims, Lilly James (L1724) and Dominion (L1728). Quadex Resources Ltd. of Vancouver, B.C. optioned the SET 1 and SET 4 claims from Mervin Boe.

In July 1983, Dr. W.D. Groves, P.Eng. investigated the SET 1 and 4 claims for Quadex Resources. Since then exploration on the property has been continued to date as summarized below.

In October 1983, Dr. W.D. Groves, P.Eng. and Nielsen Geophysics Inc. carried out geological, geochemical and VLF-EM surveys covering 10 lines 1,500 m in length and spaced 250 m apart at a station interval of 25 m. A total of 99 samples were analyzed for Cu, Zn, As and Au, on the line grids, 100 m spacing, 500 m apart.

In July 1984, B. Taylor, P.Eng. and Greg Huizen, P.Eng. performed generalized geological mapping and geochemical survey on the northeast portion of the SET 1 claim only. A small grid was marked out, totalling four line km. 87 soil samples were geochemically analyzed for 11 elements including gold.

In January 1985, L. Sookochoff, P.Eng. conducted a geological evaluation on the Set 5 claim. A three stage exploration program of geochemical, geophysical and geological surveys and subsequent trenching and diamond drilling was recommended.

In October-November 1986, geological, geochemical and geophysical surveys were completed by Ossa Resources mainly on the SET 4 and SET 5 claims.

Development on the property is limited, composed mainly of short adits and shallow shafts in the Overlander Workings in the northeast and Lookout claims, about 1,000 m west of the Overlander Workings. These prospect shafts and adits were apparently developed in the late 1950's. The Overlander Workings, in which a narrow but persistent northwest-trending structure with significant gold values is traced over a strike length of 200 m, is first reported by V. Cukor, P.Eng. in February 1983 for Corinthian Resources Ltd. Cukor (1983) showed the mineral occurences (Overlander) as located on a crown granted claim (Lookout - L930). However, the location of this showing should be revised to the present position as set out in this report.

GEOLOGY

A 1985 Provincial Map No. 59 accompanying paper, "Geology and Mineralization in the Mount Attwood - Phoenix Area" by B.N. Church updates the regional geologic information in this area. A portion of this map is presented in this report. As indicated on the map, the Triassic Eholt Formation of the Brooklyn Group, occupying most area of the property, is in fault contact with older Attwood and Knob Hill Group rocks of Permo-Carbonifeorus age. Church (1985) gives specifically a geological description related to the SET 1 claim geology:

"A relatively complete, but apparently inverted and down faulted, Triassic section (Brooklyn Group) is viewed on the upper slopes of Mt. Attwood one kilometer southwest of the east summit. At this location a wedge of Brooklyn limestone (8) about 50 meters thick and dipping westerly, is sandwiched between Eholt Volcanics (9) structurally below, and a 110-meter-thick cap of sharpstone conglomerate (7) above."

MINERAL OCCURENCES

On the SET property two types of mineralization are known to occur: skarn and shear zone associated mineralization with quartz veining. A brief description is as follows:

Skarn Mineralization

On the line grid coordinates of 1000 E and 900 N, an old mine dump site is located at and immediately below the all weather mine-haulage road to the Lone Star mine. This location is coincident with the position of an abandoned mine shown on topo map NTS 82E/2E. The dump materials at this location include typical skarn-sulphide mineralization similar to that at the Phoenix open pit or Snowshoe Workings. Minerals consist of chalcopyrite, pyrrhotite, malachite, bornite and pyrite with lesser sphalerite, galena and molybdenite. The gangue minerals are quartz, carbonate, garnet, epidote and possibly apatite on a megascopic inspection.

To the southwest of Mt. Attwood, north of Baseline 1500 N between lines 0+00 and 200 W, limestone and an argillite member of the Brooklyn are intruded by Cretaceous granodiorite resulting a lime-silicate alteration with local skarnification.

Although no economic mineralization is encountered on surface in this skarnized area to date, a potential for classical skarn type mineralization seen elsewhere may not be precluded at depth, analogous to a metallogenic model depicted by B.N. Church.

Mineralized Shear With Quartz Veining

This type of mineralization is represented by the Overlander Showings. B.N. Church (1985) gives a plausible note as to a metallogenic model related to the Overlander Showings:

> "The intricate and extensive fissure system of the Mt. Attwood-Phoenix area provided the neccessary channelways leading metaliferous solutions to the ore deposits. In this model the igneous intrusions (Greenwood granodiorite stock) served principally as heat engines in the process of convection and dispersion of the solutions."

GEOCHEMICAL SURVEYS

1. Field work

Recce geochemical surveys were carried out on the property on a north-south 50 and 100 meter grid with samples taken at 25 meter intervals along the grid lines. Samples were selected from the B horizon (commonly 20-30cm) of the brown forest soil. A total of 776 samples were taken and sent to Acme Analytical of Vancouver for analysis.

2. Testing Procedure

The testing procedure is first to thoroughly dry the sample. Then .500 grams of material is digested with 3 ml. of 3:1:3 HCL to HNo3 to H2O at 90 deg. more or less for one hour. The sample is diluted to 10 mls. with water. The samples were then analyzed by atomic absorption for 30 elements.

3. Treatment of Data

In assessing the data results, the background, sub-anomalous and anomalous values were determined utilizing a statistical software program on an IBM personal computer.

The sub-anomalous threshold value, which is a value not considered anomalous, but an indicator of potential mineralization, is taken as one standard deviation from the mean background value. The anomalous values or the prime indicator vlaues are taken at two standard deviations from the mean background values.

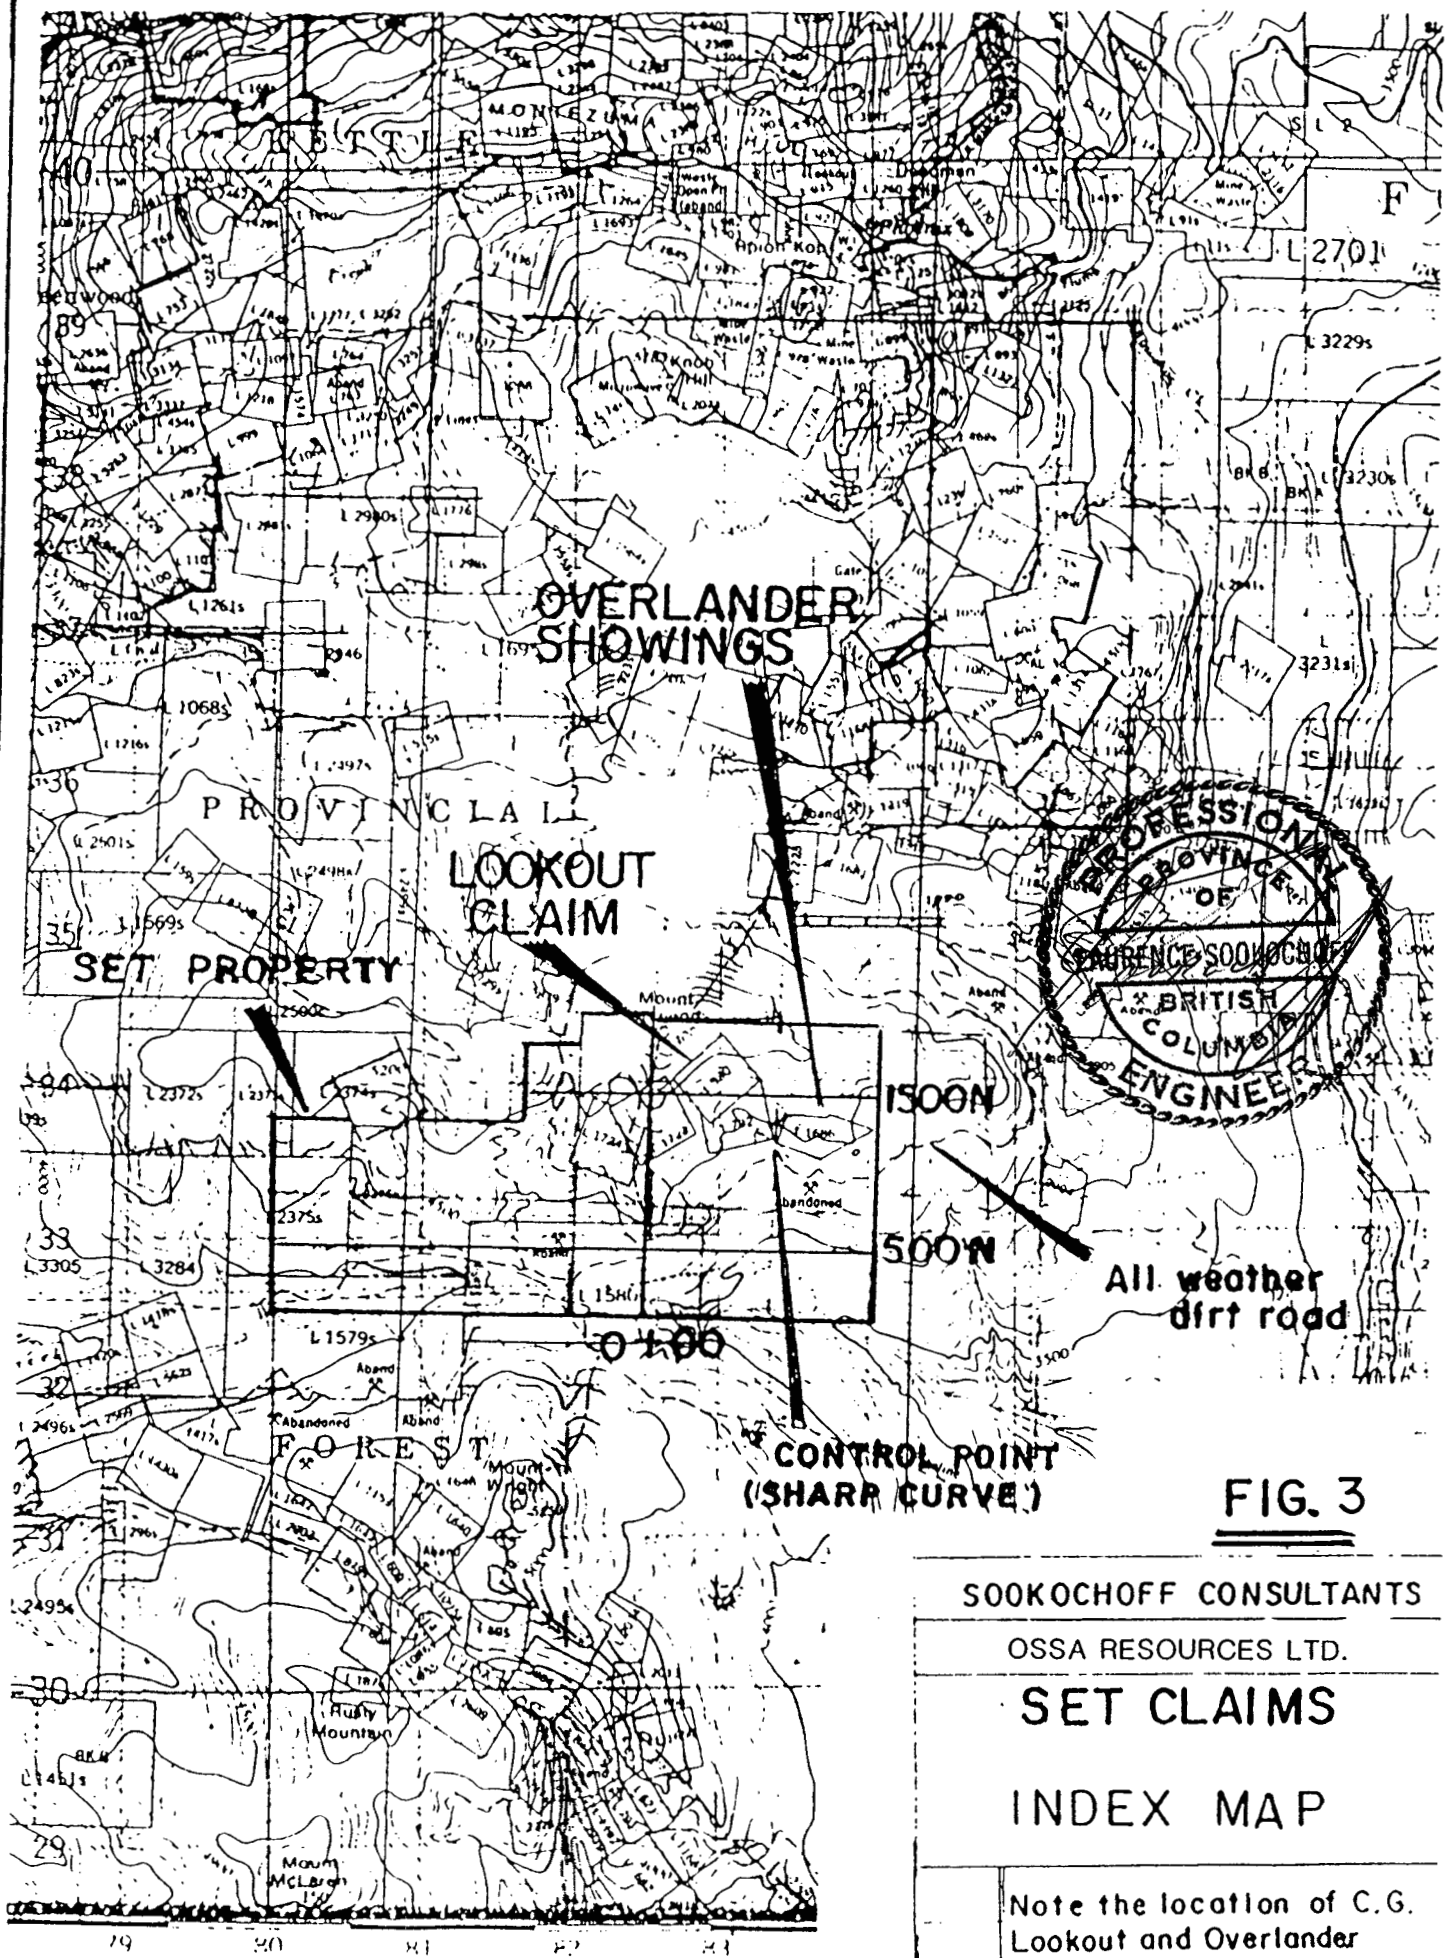

FIG. 3

SOOKOCHOFF CONSULTANTS

OSSA RESOURCES LTD.

SET CLAIMS

INDEX MAP

Note the location of C.G. Lookout and Overlander Showings relative to control point and line grids

The results of the data treatment for five elements were as follows:

	Cu	As	Zn	Pb	Ag
Mean background	29.3	14.0	79.6	13.8	.19
Sub-Anomalous	45.4	25.3	116.4	20.6	.31
Anomalous value	61.5	31.6	153.2	28.2	.42

All values are in parts per million.

4. Results

In plotting the geochem results one prime correlation anomalous area "A" and a cluster of correlative anomalous zones in areas "B" were delineated.

Anomaly A - is basically a one line (1400N) 200 meter long (N-S) anomaly open to the north with fingers extending westward to line 1200 N. The anomaly occurs in proximity to and to the east of the Overlander workings where a 120 meter long gold bearing mineralized quartz vein occurs. The anomaly is of basic anomalous arsenic values (736.6 ppm in a background of 14 ppm) with correlative anomalous zinc values over two lines open to the north.

Outcrop is absent in the anomlous area. The causative source of the anomaly can only be suggestive of an intrusive or skarn zone with the potential of arsenopyrite bearing (and gold?) minerals. The anomalous area indicates potential mineral bearing east-west structures (fracture zones?) with possible down slope contamination. The Overlander workings could occupy a complementary set of northerly trending structures.

Anomalous area B consists of a number of isolated anomalies with occasional double line occurrences of single or multielement anomalies. The northern anomalies of primarily zinc and/or lead and rare silver occur within a skarned area peripheral to two known granodiorite plugs. A shaft containing rusted bleached rock near the south plug occurs within a zone of schists. Portions of the schists - where mapped - correlate with copper and/or lead and/or silver anomalies.

GEOPHYSICAL SURVEY

VLF-EM Survey

The survey was carried out over the same grid as was utilized for the geochemical survey. 1325 readings were taken at 25 meter intervals for each of the VLF and magnetometer surveys.

A sabre Model 27 VLF-EM Receiver instrument manufactured by Sabre Electronics of Vancouver was utilized in the VLF-EM survey.

The VLF-EM Receiver measures the amount of distortion produced in a primary transmitted magnetic field - in this case Seattle at a frequency of 24.6 Khz - and a secondary magnetic field which may be induced by a conductive mass such as a sulphide body. The VLF-EM unit - due to its relatively high frequency - can detect low conductive zones such as fault or shear zones, carbonized sediments or lithological contacts.

The major disadvantage of the VLF method, however is that the high frequency results in a multitude of anomalies from unwanted sources such as swamp edges, creeks and topographical highs.

The results were Fraser filtered in plotting the VLF-EM results. The raw field data is appended.

The VLF-EM survey delineated a general east-west anomalous zone in the north correlating with a mapped chlorite and/or amphibolite and related schist zones. Two strong east-west anomalies correlate with the geochemical anomalous area A substantiating the indicated east-west trending geochemical "finger" zones.

Other anomalous zones could not be interpreted mainly due to lack of geology and geochemical expression in the southern portion of the claim group where excessive overburden provides a masking effect.

A power line passing east-west across the south of the property is the cause for the erratic values in that area.

MAGNETOMETER SURVEY

The magnetometer survey was carried out utilizing a Model G-10 fluxgate magnetometer manufactured by Geotronics Instruments of Vancouver. Diurnal variation was checked by periodically comparing readings at the base station.

All rocks contain some magnetite from very small fractions of a percent up to several percent, and even several tens of percent in the case of magnetic iron deposits. The distribution of magnetite or certain characteristics of its magnetic properties may be used in exploration or mapped for other purposes.

The anomalies from naturally occurring rocks and minerals are due chiefly from the presence of the most common magnetic mineral magnetite or of related minerals including limonite and pyrrhotite (with sulfide mineralization).

Magnetic anomalies in the earth's magnetic field are caused by two different kinds of magnetism: induced and remanent. Induced magnetization refers to the action of the field on the material wherein the ambient field is enhanced and the material itself acts as a magnet.

The proportion of magnetism is related to the magnetic susceptibility of the material. Typically, more basic igneous rocks have a higher susceptibility than the acid igneous rock; the latter in turn have a higher susceptibility than sedimentary rocks.

The remanent magnetization is often the predominant magnetization (relative to the induced magnetization) in many igneous rocks. The remanent mineralization is important in geological mapping.

Magnetic minerals may also occur in association with sulphide zones or may be decomposed through the action of dynamic or thermal metamorphism. Thus the survey results could indicate lithology, structure, alteration patterns and most significantly, mineral zones in a favorable geological environment.

In the prime correlative anomalous area B the magnetometer survey disclosed a series of peripheral mag lows to the north and west and to a lesser extent to the southeast where an absence of outcrops makes interpretation difficult. A southeast and southwest mag low correlates with a schist, thus indicating the other mag lows may be shear related structures. If such were the case, a mag low correlating with anomalous zinc and lead values at 1900 N and between 100 W and 400 W should be examined for structurally controlled mineralization. A similar more localized area of a mag low in an anomalous schist area would be of similar interest.

In anomalous area A a small mag low occurring at the western extent of a finger of anomalous silver-lead-arsenic values and correlating with a VLF-EM anomaly would be of interest.
