1.0 SUMMARY

The Platinum Blonde property is owned by Longreach Resources Ltd. and it is under option to Placer Dome Inc. The property covers a portion of the Franklin Mining Camp in the Grand Forks area of Southeastern British Columbia. The property includes a variety of mineral showings which have been explored intermittently since the early 1900's.

Placer Dome Inc. conducted a ground exploration program on the property between April and October, 1987. The program included (1) the construction of approximately 182 line km of grid; (2) geological mapping at 1:5,000 and 1:2,500 scale; (3) outcrop and trench sampling (295 samples); (4) conventional (5134 samples) and bulk (96 samples) soil sampling programs; (5) ground geophysical (VLF and Magnetometer) surveys and (6) a 10 hole 1,209 metre diamond drill program.

Three styles of mineralization were encountered on the property: (1) Fe, Cu and/or As mineralization occurs in skarn derived from calcareous sedimentary and volcanic strata peripheral to igneous plutons; (2) Cu, Ag, Pt and Pd mineralization (Averill, Mapleleaf) occurs in chalcopyrite rich segregations and veins in intrusive rocks which belong to a multiphase alkali plutonic complex ("Averill Alkali Complex"); (3) Ag and/or Au, Ag, Pb, Zn, Cu mineralization (Laura, Homestake, Union) occurs in a series of late quartz veins which cut a package of deformed volcanic and sedimentary strata immediately below a major uncomformity.

The exploration program carried out in 1987 has helped to clarify the stratigraphy, structure and nature of the mineralization found within the Franklin Mining Camp. No new mineral occurrences of any obvious significance were encountered in the course of the program. Some of the known showings (Averill, Laura, Jimmy, Mapleleaf and Union) were drill tested. The holes failed to intersect significant mineralization.

2.0 INTRODUCTION

2.1 Location and Access

The Platinum Blonde property covers much of the Franklin Mining Camp in the Greenwood Mining Division of Southeastern British Columbia. It consists of a complex land package on and around Mt. Franklin in the Central Monashee Mountains. The property lies at the junction of Franklin Creek and Burrell Creek (latitude 49° 33'N, longitude 118° 22' W) approximately 65 km due north of the community of Grand Forks (Figure 1).

The property is accessible by road. The North Fork road is a black topped highway which follows the Granby River to the north of Grand Forks. The Burrell Creek road joins the North Fork road at km 48. The latter is a major haulage road which runs up Burrell Creek. At km 25 there is a 2 km long access road which extends from the main logging road to the Platinum Blonde campsite at the Union Mine. There is good four-wheel drive road access throughout the land holding. All the principal mineral showings are accessible by road.

Mt. Franklin is a rugged, mountainous knob (elevation 1450m) which separates Franklin Creek from Gloucester Creek and the Burrell River (Figure 1). Its slopes are locally well exposed although substantial areas are covered by till and colluvium. These areas are forested or grassed over. The valley floors are flat bottomed and choked with till and alluvium.

2.2 Property Status

The Platinum Blonde property consists of a complex assemblage of active and reverted crown granted claims and two and four post claims which are either owned outright or held under option by Longreach Resources Ltd. (# 605 - 475 Howe Street, Vancouver, British Columbia, V6C 2B3). The claims controlled by Longreach are listed in Table 1 and they are shown in outline on Figures 2 and 3. The Platinum Blonde property covers some of the main mineral showings which make up the Franklin Camp. These include the Mapleleaf, Averill and Buffalo platinum and palladium occurrences and the Laura and Jimmy vein deposits. The land holding does not include any of the mineral occurrences on the Mountain Lion, Gloucester, G.H., Union, Banner, Bullion or Homestake claims. Longreach Resources is negotiating to acquire most of the missing crown grants within its current land holdings and it has received permission to conduct limited surficial exploration on these claims while negotiations were being carried out.

Longreach Resources has reached an agreement with Sumac Ventures Inc. whereby the Company has been granted the right to explore for a faulted off-set to the Union vein on ground which is currently held by Sumac.

Longreach Resources acquired most of its ground in the Franklin Camp in 1986 and it conducted a preliminary exploration program on the property in the same year. The program consisted of a series of detailed geophysical surveys which were carried out in the vicinity of the main platinum and palladium showings. These were followed by a

1,868 metre diamond drill program comprised of 31 holes collared to test the extent of the mineral showings. Placer Dome Inc. optioned the property from Longreach Resources in October, 1986. The Company logged, sampled and assayed the Longreach drill core prior to conducting a major exploration program on the Platinum Blonde property in the summer of 1987.

2.3 Development History

The Franklin Creek area was identified as an area of widespread mineralization in the early 1900s. Most of the currently known mineral occurrences had been identified and several had received a considerable amount of trenching and development work by the time C. W. Drysdale of the Geological Survey of Canada mapped the area in 1911 (G.S.C. Memoir 56; "Geology of the Franklin Mining Camp, British Columbia"; 1915). Drysdale recognized several styles of mineralization within the Camp. These include (1) occurrences of platinum and palladium bearing chalcopyrite mineralization within or peripheral to "black lead", a pyroxenite phase of a major alkalic intrusion complex; (Mapleleaf and Averill): (2) contact metamorphic skarn deposits formed where calcareous volcanic and sedimentary rocks of the Franklin Group are cut by younger intrusions (Gloucester, Mckinley) and (3) "high-grade" precious and base metal deposits associated with a suite of late guartz veins (Union, Homestake).

The Mapleleaf occurrence produced a small amount of ore rich in copper, silver, platinum and palladium in the early years and the Union Mine has seen intermittent gold and silver production. The mine was in operation between 1913 and 1946.

The complex alkalic intrusion which underlies the Franklin area was partially explored for its "porphyry copper" potential in the 1960s. Franklin Mines Ltd. explored part of the complex in 1965 (Assessment Report 637) and Newmont Mining Corporation of Canada conducted a regional program in the area in 1968 (Assessment Report 1845).

The Union Mine is currently held by Sumac Ventures Inc. The company conducted surface and underground drill programs on the property in 1985 and 1986 and established a leach plant on the property in 1987.

Most of the mineral occurrences in the Franklin Camp are not well documented and they appear to have seen very little recent exploration.

3.0 REGIONAL GEOLOGICAL SETTING

The Franklin Creek area is located in a geologically complex portion of the Canadian Cordillera. The area has most recently been mapped H. W. Little (G.S.C. Map 6-1957). Figure 4 is a simplified geological map of the Burrell Creek area after Little, 1957. The oldest rocks in the vicinity of the property comprise a package of hornfelsed volcanic and sedimentary strata which are assigned to the Palaeozoic age, Anarchist Group (Unit 3). The package occurs as isolated pendants and remnants engulfed in a large variety of younger batholiths and plutons. These include Mesozoic intrusions of calc alkaline affinity associated with the Nelson (Unit 6) and Valhalla (Unit 7) batholiths and Cenozoic alkalic intrusions which belong to the Coryell batholith suite (Unit 8).

The region underwent uplift and deep erosion during the Eccene period prior to an extensional event which caused tectonic collapse and the development of a series of grabens. The Franklin Camp lies at the north end of the Republic Graben, a structure which extends into the United States south of Grand Forks.

The graben locally filled with coarse mollasse sediment which is assigned to the Kettle River Formation (Unit 9). This was subsequently covered by alkalic, trachytic, volcanic strata of the Phoenix volcanic suite (Unit 10).

There has been a considerable amount of block faulting in the vicinity of Franklin Camp. The rocks are cut by a series of major, north-south oriented, faults. These underlie most of the principal valleys in the region.

4.0 WORK PERFORMED

4.1 Introduction

The 1987 field program on the Platinum Blonde property had two principal objectives. These were (1) to assess controls and significance of the known platinum and palladium mineralization on the property and (2) to evaluate the relevance of the large number of precious-metal bearing guartz veins in the area.

Work on the Platinum Blonde property commenced in April and continued until October, 1987. The project included (1) the preparation of topographic base maps at 1:5,000 and 1:10,000 scale; (2) the construction of a 182 line km grid covering almost the entire property; (3) extensive prospecting and trench sampling; (4) detailed geological mapping; (5) a 5,134 sample soil geochemical survey; (6) a 96 sample bulk soil geochemical survey; (7) a VLF and magnetometer survey and (8) a 10 hole (1,209 metre) diamond drill program.

The Platinum Blonde grid was established in relation to a central, north-south oriented, tieline (L53+00E) and four, east-west oriented, baselines (L38+00N, L55+00N, L65+00N and L75+00N). The lines were professionally cut and picketed at 50 metre intervals. North-south oriented gridlines were established by means of compass and hipchain. The lines were put in at 100 metre intervals and they were tied to the baselines during and after construction of the grid. Grid stations were marked with flagging and luggage labels at 20 metre intervals. Figure 3 shows the theoretical grid at 1:10,000 scale. In reality, the grid was found to deviate considerably from the ideal configuration and a considerable effort was put into defining the shape of the grid. Subsequent figures, at 1:5,000 scale, show the best-fit configuration of the grid.

The Homestake and Mapleleaf areas were found to be poorly served by the original grid and secondary grids were established in these areas. The Homestake and Mapleleaf grids were constructed in a similar manner to the Platinum Blonde grid but a considerable effort was taken to ensure that the lines did not wander. The two grids, outlined in Figure 3, have their own coordinates and they are marked with different colours of flagging.

Geophysical and geochemical surveys were carried out on the main grid. The secondary grids were used to improve the quality of mapping in two areas which were known to be of economic interest. The Homestake grid was used to tie in the various adits, pits and trenches found in the vicinity of Homestake showing. The Mapleleaf grid was also used in locating four of the ten holes drilled on the property.

The presence of platinum and palladium in alkalic rocks of the informally named "Averill Alkali Complex" has been known for some time. The distribution and significance of the mineralization is, however, poorly understood and several agencies initiated academic studies on different aspects of the mineralization during the summer field season. Dr. J.K. Russell and Dr. W.K. Fletcher of the Department of Geological Sciences at the University of British Columbia initiated detailed petrological and lithogeochemical studies (Dr. J.K. Russell) and a preliminary review of the distribution of platinum group elements in soil (Dr. W.K. Fletcher). The mineral showings were examined and sampled by Dr. L. Hulbert of the Geological Survey of Canada. The samples will be used in an on-going review of trace element and isotope contents of Cordilleran platinum and palladium occurences.

The Union vein has also received a considerable amount of attention. Dr. R.D. Russell and staff from the Department of Geophysics and Astronomy at the University of British Columbia conducted a series of piezoseismic tests designed to locate a faulted extension to the Union vein hidden under a cover of Kettle River formation arkose.

4.2 Property Geology

The main Platinum Blonde grid was used to generate a preliminary geological map of the property. The map was later augmented by more detailed mapping carried out on the Homestake and Mapleleaf grids. The mapping was conducted Dr. A. Sutherland Brown.

Figures 5 (W,E) show the geology of the western and eastern halves of the property area at 1:5,000 scale and Figures 6 and 7 show the geology of the Homestake and Mapleleaf grid areas at 1:2,500 scale. Figure 8 is a schematic north-south oriented cross section showing the facies relationships observed in Franklin Group strata on and to the south of the Homestake grid.

4.2.1 Stratified Rocks.

The stratified rocks in the property area are comprised of four separate units. The area is underlain by remnants of a volcano-sedimentary basement which is assigned to the Palaeozoic, Franklin (Anarchist) Group (1). This basement was invaded by plutonic rocks during the Mesozoic period and underwent extensional tectonism and deep erosion prior to deposition of Eocene age graben-fill sediment belonging to the Kettle River Formation (2). Sedimentation in the property area terminated with the eruption of a local rhyolitic volcanic centre. This unit is referred to as the McKinley Rhyolite Member of the Kettle River Formation (3). The rhyolite is overlain by a thick succession of trachytic volcanic flows which belong to the Marron (Phoenix) Formation (4).

Franklin Group

The Franklin Group consists of a sequence of sedimentary and volcanic rocks that have been subjected to multiple deformations and fairly intense thermal metamorphism. The Group appears to consists of subequal proportions of sedimentary and volcanic rock. Many units are difficult to classify as they grade between hornfelsed tuff, tuffite and listric sandstone. The group is widely distributed in the property area and shows a considerable variability in local facies. Individual rock units are traceable for short distances and it is possible to set up an informal stratigraphy for specific areas.

The following stratigraphy was constructed for the

FVb = andesitic tuff breccia	Fp = crowded feldspar hornblende porphyry	
<pre>Fvd = dacite tuff and flows</pre>	<pre>Fpt = feldspar porphyry tuff</pre>	
Fsa = arkosic and quartzose sandstone	Fa = black to buff argillite	
Fc1 = quartzose grannule conglomerate	Fac = black to buff chert and cherty sandstone	PLACER DO
Fc2 = heterolithic conglomerate	Gp = grey porphyry	PLATINUM BLON
		SCHEMATIC GEOLO HOMESTAKE

1

)

area of the Homestake grid. It assumes that the rock units face east and that there is only minor structural repetition within the package. The following units are encountered from the top down.

Fvb: - a grey green massive-looking volcanic unit of andesitic composition with feldspar phenocrysts 1 mm in diameter. The rocks are predominantly lapilli tuffs and fine tuff breccias. Most of the larger clasts are one to three cm in diameter.

Fvd: - a grey to greenish grey lapilli tuff to tuff breccia with recognizable quartz phenocrysts in both clasts and matrix. The unit occurs at the same stratigraphic horizon as unit Fvb: (above) and it interfingers with it. The unit predominates to the south of the Homestake grid.

Fsa: - a greenish grey to pinkish grey weathered fine to medium and rarely coarse grained sandstone. The rock is usually well graded and some grains are rounded. It consists mainly of fragments of feldspar and quartz but it also includes mafic and listric clasts. Some samples are finely banded. The rock is derived from a volcanic source and, where hornfelsed, it is often difficult to distinguish from a volcanic rock.

Fsv: - a green lithic volcanic facies of the above sandstone. This particular facies is relatively uncommon in the vicinity of the Homestake grid but it is widely distributed elsewhere.

Fpt: - a tuffaceous feldspar porhyry facies of the sandstone
unit.

Fc: - a heterolithic conglomerate unit that is variable in character. It contains well rounded clasts of limestone, quartz and black chert in in a matrix of argillite. The clasts are usually small (1.0 - 5.0 cm) but the conglomerate contains locally derived limestone fragments up to 1.0 metre in diameter. The conglomerate is intermixed with finer material in the form of lenses of quartz pebble conglomerate and interbeds of well banded fine to medium sandstone (Fsa:). The unit may have formed when blocks of limestone slumped into a sedimentary basin. It occurs at two stratigraphic horizons in the Homestake area. The upper unit is generally finer grained (pebble conglomerate) and it contains appreciably less limestone.

Fp: - a light green, fresh-looking, commonly crowded, hornblende feldspar porphyry. The rock contains 25 - 35% of 1.0 - 2.0 mm feldspar crystals and 2.0 mm hornblende phenocrysts. The unit consists of a complex assemblage of massive dykes, sills and/or flows. Locally it includes lapilli tuff (Fpt:) which passes gradationally to volcanic sandstone (Fsa:) and tuffaceous argillite (Fat:).

Fl: - a blue-grey, sugary, recrystallized, cliff-forming limestone unit which forms a useful marker horizon in the vicinity of the Homestake grid. The unit was mapped as the Gloucester limestone by Drysdale.

Fa: - black to bleached fine sediment which ranges from argillite through cherty siltstone to chert (Fac:). The unit is locally intensely fractured and the fractures are coated with pyrite. The unit is commonly thermally metamorphosed to a biotite guartz hornfels.

The structure of the Franklin Group package is not clearly defined. Most of the strata in the Homestake area strike within 15° of north and dip steeply to the east. There is no simple explanation for the apparant rotation of the stratigraphic package at the north end of the Homestake grid. Folding has not been recognized as an important feature within the package. There is however clear evidence for several episodes of block faulting. These faults have caused local stratigraphic off-set and they control much of the late epigenetic mineralization.

Kettle River Formation

The Kettle River formation consists of a thick package of rapidly deposited graben-fill sediment which was deposited unconformably on an eroded basement of Franklin Group and intruded plutonic rock. The unit is divided into two principal facies. These are fanglomerate (Kf:) and arkose (Ka:).

Ka: - a buff, cream to light greenish grey, water lain, arkose unit. The arkose consists of poorly sorted angular to subangular fragments in parallel bed-sets which can be distinguished by grain size. The arkose is interbedded with siltstone and pebble conglomerate. Individual beds are massive and structureless. The beds show no sign of cross bedding, chanelling or internal grading. The arkose is largely comprised of feldspar. It appears to contain 30% of both orthoclase and plagioclase feldspar as well as variable amounts of quartz (10 - 25%), listric fragments (5 - 20%) and mafic minerals (5 - 15%). The unit is probably derived from the breakdown of the underlying syenite complex. The proportions of fanglomerate and arkose found in the Kettle River formation varies across the property. Fanglomerate is most abundant in the northern and southern parts of the map area where the overall unit is at its thickest (150 metres). In these localities the fanglomerate unit contains basal and superior arkose bands up to 25 metres thick. Fanglomerate is less well developed where the overall thickness of the unit is less (40 metres), as in the vicinity of the Mapleleaf showing.

The Kettle River formation is well exposed on Mt. Franklin where it forms an easterly dipping cover to rocks belonging to the Franklin Group and the Averill Alkali Complex.

McKinley Rhyolite

The McKinley Rhyolite is an informal name for an ephemeral unit which occurs at or near the top of the Kettle River Formation. It occurs on the ridge which extends south from L55+00E 38+00N on the Platinum Blonde grid and it occurs at the northeast end of Mt. Franklin at L56+00E 67+00N on the same grid.

The unit combines sedimentary and pyroclastic features. It consists of a rhyolite flow or flow breccia which locally incorporates fanglomerate roundstones and appears to grade into arkose.

Kr: - a crowded rhyolite porphyry flow or flow breccia which contains 10% of clear, coroded, quartz, 20% of feldspar crystals and 2.0% of biotite phenocrysts in a chalky white matrix. The phenocrysts are up to 5.0mm in diameter.

Marron Formation (Phoenix Group)

The Marron formation overlies the Kettle River conformably or without significant unconformity. It consists of a thick (100 metres) succession comprised of a large number of superimposed, massive, trachyte flows.

T: - a lightish purple grey to greenish grey, sparsely porphyritic, trachytic volcanic rock which contains up to 10% of phenocrysts. These include clots of mantled feldspar up to 5.0mm in diameter and somewhat smaller altered pyroxene crystals. The phenocrysts define a weak trachytic texture in what is otherwise an aphanitic volcanic matrix.

4.2.2 Plutonic Rocks

The plutonic rocks in the map area are widespead and diverse in nature. They have been divided into six separate plutons and two descrete dyke swarms. The intrusions probably range in age from Jurassic equivalents of the Nelson Batholith to late Eocene hyperbyssal equivalents of the Coryell Batholith. The suite includes rocks which belong to both alkali and calc alkali magma series.

The oldest plutonic rock in the map area is refered to as the Gloucester Pluton (G1/G1a:). This unit can be seen to intrude and hornfels Franklin Group strata. The Gloucester pluton, which is calc alkaline in character, is demonstrably cut by a variable suite of alkalic rocks which are informally assigned to the Averill Alkali Complex (S,CTS/TS,Px,MD/MG,M). The complex is itself cut by a younger suite of calc alkali plutons. These include the West Fork (G2), Grey Porphyry (GP), Bluejoint Mountain (G3) and Aldie (D) plutons. The map area appears to have undergone substantial uplift, erosion and deposition of the Kettle River Formation prior to emplacement of the two main dyke swarms. These consist of alkali Pulaskite Porphyry (Pu) and calc alkali granodiorite of the North Plateau Pluton.

The Averill Alkaline Complex is comprised of a complicated assemblage of clearly related alkalic intrusions. The distribution of the various phases allows one to develop a tentative model for the formation of the complex as a whole. The data indicate the presence of an early, zoned, monzonitic intrusion (MD/MG,M) which differentiated to form a basal pyroxenite cumulate (Px). This early intrusion was intruded more or less penecontemporaneously by a fine to medium grained, trachytic, pyroxene syenite (S) which cooled slowly to form a coarse grained, locally trachytic, syenite core (cTS,TS).

Lenses of pyroxenite and monzogabbro derived from the initial intrusion appear to have been intruded upward into the younger symplex.

Gloucester Pluton (G1/G1a:)

The Gloucester pluton consists of a fine to medium grained, chloritized, hypidiomorphic hornblende granodiorite. It appears to contain 15 - 20% hornblende, 15 - 20% quartz, 15% orthoclase and 45% plagioclase in a fine grained matrix. The grain size is commonly 2.0mm. The rock becomes finer grained on its northeast border (Gla:).

Averill Alkali Complex: Early Phase (Px, M, MD, MG)

The complex consists of gradational package of monzonitic rocks which are subdivided on the basis of mafic mineral content into Pyroxenite (Px) which contains 90 - 100%, Monzogabbro (MG) which contains from 65 - 90%, Monzodiorite (MD) which contains from 35 - 65% and Monzonite (M) which contains 15 - 35%.

Pyroxenite has a variable texture and composition. It is commonly medium grained (3.0mm) consisting of elongated pyroxene crystals set in a matrix of altered feldspar. The feldspar matrix and much of the pyroxenite is commonly altered to biotite.

Monzonite is invariably fine grained (1.0mm) and it contains up to 5% of coarse (5.0mm) phenocrysts of pyroxene and plagioclase. Biotite is rare. Monzodiorite is normally fine grained (1.0 - 3.0mm) with a slightly foliated fabric. Monzogabbro is medium grained (2.0 -4.0mm). It commonly contains larger, oriented, schlieren of pyroxene and feldspar. Syenite veins cutting monzogabbro commonly display metasomatic envelopes consisting of randomly oriented crystals of pyroxene.

Averill Alkali Complex: Late Phase (S, CTS, TS)

The late phase of the syenite complex consists of a medium (5.0mm) to coarse (20.0mm), locally pegmatitic (80.0mm), pyroxene syenite (S). The rocks consist of 70 - 90% orthoclase laths with 10 - 30% pyroxene which occurs either in interstitial spaces or as parallel prisms. The syenite has a trachytic varient (cTS,TS) which displays a pronounced flow banding of the euhedral feldspar laths. Medium grained trachytic syenite is well developed in the vicinity of the Mapleleaf mineral occurrence.

West Fork Pluton (G2)

The West Fork pluton consists of a body of medium grained (3.0 - 4.0mm) hypidiomorhic hornblende granodiorite. The rock consists of 20% hornblende, 45% plagioclase, 15% orthoclase, 15% quartz and 5% biotite. There are minor granitic and aplitic (G2a) phases within the pluton.

Grey Porphyry (GP)

The grey porphyry body is comprised of spotted grey and white porphyry. This contains 30% of zoned plagioclase feldspar laths, up to 2.0mm in diameter; 5% of small phenocrysts of biotite and rare (2.0 - 4.0mm)
corroded quartz grains in a dense, grey, glassy matrix.
The porphyry may be a late phase related to the West Fork
pluton.

Bluejoint Mountain Pluton (G3)

The Bluejoint Mountain pluton consists of a coarse (5.0mm) pink allotriomorphic granite which contains approximately 70% of subequal amounts of plagioclase and orthoclase feldspar, 20 - 25% of large, irregular, quartz crystals with approximately 5% of both hornblende and biotite. Border phases are variable in composition and texture. They include aplitic (G3a) and sphene bearing (G3f) varieties of granite.

Aldie Pluton (D)

The Aldie pluton is comprised of a fine grained (1.0 - 3.0mm) weakly foliated leucocratic diorite. This is made up of approximately 75% of zoned laths of plagioclase; 15 - 20% of hornblende and 5 - 10% of guartz.

Pulaskite Porphyry (Pu)

Pulaskite occurs as resistent dykes of buff weathering porphyritic mafic syenite. This contains approximately 20% of glomeroporphyritic to radiating mineral clots in a fine to aphanitic matrix. The clots consist of orthoclase with biotite and pyroxene.

North Plateau Pluton (G4)

The North Fork pluton consists of a fine to medium grained (1.0 - 3.0mm) hypidiomorphic hornblende granodiorite. The rock is comprised of 45% plagioclase, 15 - 20% of both quartz and hornblende and 15% of orthoclase.

4.3 Structure

The Mt. Franklin area has undergone several episodes of brittle deformation which have profoundly influenced both the geological structure and the topography of the map area. Faults have been identified running northwest-southeast, northeastsouthwest, north-south and east-west. These structures are best developed in the oldest rocks in the map area (Franklin Group) but there is a good evidence to indicate that some early structures were reactivated after the deposition of the Marron formation.

The Franklin Group strata are cut by a prominent set of east-west oriented structures, one of which hosts the mineralized guartz vein at the Union Mine. The vein appears to have formed prior to erosion of the Franklin Group and deposition of the Kettle River Formation. A similar structure on the Mapleleaf claim appears, from geophysical data, to be traceable across the Marron formation on Mt. Franklin into the headwater of Twin Creek. The east-west oriented structures are cut by a series of major, young, commonly valley forming, north-south oriented normal faults. The Mapleleaf fault dips to the west at 50°. Movement on the fault has caused Kettle River and Marron formation strata to be downdropped to the west, along with any underlying mineralized extensions to the Union and Mapleleaf structures. Geological and geophysical data suggest that some of the larger east-west oriented structures are intruded by dykes derived from the Aldie Pluton (D).

4.4 Mineralization

The three types of mineralization recognized by C. W. Drysdale have all been identified on the Platinum Blonde Property. These are (1) small lenses of magnetite, pyrite, pyrrhotite, chalcopyrite and/or, locally, arsenopyrite bearing skarn in brecciated and altered Franklin Group volcanic and sedimentary strata peripheral to the Gloucester Pluton and rocks of the Averill Alkali Complex; (2) platinum, palladium and silver were found in association with chalcopyrite in pyroxenitic and sygnitic phases of the alkali complex and (3) silver and/or gold was found with or without base metal mineralization in silcified shears and faults.

The Platinum Blonde property was prospected for each deposit type. Trenches were located throughout the property. These were mapped and, where mineralized, they were sampled. Most of the trench samples are random chip samples of mineralized material. Isolated outcrop samples are either random chip or hand specimen samples. Trench and sample locations are shown in Figures 9 (W,E) and 10.

A total of 295 samples were submitted to the Placer Dome Inc. laboratory in Vancouver for analysis. Most were analyzed for one of two suites of elements. Those samples which were collected from trenches in proximity to the alkali complex were analyzed for Cu, Zn, Pb, Ni, Ag, Au, V, As, Pt and Pd. Those which were collected from quartz veins and shears in the Franklin Group were analyzed for Cu, Zn, Pb, Ag, Au, As. A few were also analyzed for Ni, Hg, and Sb.

Most of the elements were analyzed for by atomic absorption. Arsenic was analyzed by DCP and Pt, Pd and Au contents were determined by means of a fire assay with a DCP finish. Platinum and palladium have detection limits of 20 and 10 ppb respectively. Analytical data are listed in Appendix 1 . Most elements are presented as ppm but Pt, Pd and Hg are presented as ppb. The results indicate that the property has potential for both Platinum - Palladium and Silver - Gold mineralization.

4.4.1 Platinum - Palladium Mineralization

The principal mineral showing is located on the Mapleleaf claim. Mineralization is located in a trench which marks the site of an adit which was blasted by Longreach Resources (Figures 3 and 7). At this locality platinum and palladium are found in a small 2 x 10 metre tectonic lens of chalcopyrite-bearing, coarse-grained syenite (cTS). The lens is located in hornfelsed Franklin Group strata (Fs:) and fine monzonite (M) immediately peripheral to a contact with flow banded, trachytic, syenite (TS). Contact relationships are obscure. The mineralized unit appears to consist of two phases. These are; (1) a fine grained, sugary, banded, syenite rich in disseminated pyrite, and (2) a coarse pegmatitic syenite with a variable percentage of largely interstitial chalcopyrite. The syenite is relatively fresh and it shows little evidence for extensive retrograde hydrothermal activity. Some copper may have been remobilized. Chalcopyrite occurs both on fractures and with guartz and orthoclase feldspar in veins cutting trachytic syenite and hornfelsed volcanic strata peripheral to the main showing.

Analytical data for the Mapleleaf showing are presented in Appendix 1. Representative analyses, given below, show that platinum and palladium are present in approximately equal amounts and that the overall content is crudely proportional to the amount of copper present in the rock.

Sample 22026 26,400 ppm Cu, 1,015 ppb Pt and 2,550 ppb Pd Sample 22030 21,400 ppm Cu, 1,410 ppb Pt and 1,070 ppb Pd Sample 22028 13,300 ppm Cu, 400 ppb Pt and 280 ppb Pd

The Averill mineral showing is defined by an old adit and some recent trenches put in by Longreach Resources. The showing is located in a pyroxenite (Px) body which shows clear evidence of internal disruption and invasion by younger symite (S). The pyroxenite has been biotitized and in places sulphidized along fractures. Chalcopyrite occurs as blebs in microveins of symite and as coatings on, or as disseminations within envelopes or fractures cutting the pyroxenite. In one instance

11.5

chalcopyrite was observed in a guartz vein. Analytical data in Appendix 1 again show that platinum and palladium distribution is related to that of copper.

Sample 22046 67,200 ppm Cu, 900 ppb Pt and 3500 ppb Pd Sample 22045 6,500 ppm Cu, 45 ppb Pt and 75 ppb Pd

The Buffalo platinum and palladium showing consists of some trenches and an old adit driven into sheared biotitic and locally chloritic pyroxenite which is veined by calcite. The pyroxenite is very locally cut by microveins of syenite which contain traces of chalcopyrite. No significant mineralization was encountered in the vicinity of the adit although malachite stain is not uncommon in pyroxenite in the vicinity of the Buffalo adit.

Trench and outcrop sampling only identified one new area of platinum - palladium mineralization. This occurrence was found to consist of a narrow (10 - 20 cm) east-west oriented crush zone which cuts coarse grained syenite at L41+00E 73+40N.

The shear contains a minor amount of chalcopyrite which contains some platinum and palladium (sample 22136, Appendix 1).

Sample 22136 24,200 ppm Cu, 95 ppb Pt and 650 ppb Pd

4.4.2 Silver - Gold Mineralization

Prospecting in the vicinity of the Homestake grid brought to light a large number of old pits and trenches which are scattered throughout the area of Franklin Group outcrop south of Twin Creek. Figure 10 shows the locations of the trenches and Appendix 1 lists analytical results obtained from random chip samples.

Most of the larger trenches were found to expose 1.0 - 3.0 metre wide quartz veins which cut volcanic and sedimentary strata of the Franklin Group. Some of the veins display sharp contacts. Others grade into diffuse zones of silicification, kaolinization and pyritization. Vein directions vary considerably. They follow northsouth, east-west and northwest-southeast oriented structures. The veins appear to pinch and swell and it is not always apparant what structure is controlling a particular vein. They commonly intersect. Most of the veins contain only a minor amount of pyrite although some contain appreciable amounts of galena, chalcopyrite, sphalerite and tetrahedrite. The analytical data listed in Appendix 1 show that some of the veins are rich in silver,

Sample 22053, 141 ppm Ag, 0.27 ppm Au 49 ppm Cu, 165 ppm Zn, 190 ppm Pb

Sample 22074, 196 ppm Ag, 1.51 ppm Au 25 ppm Cu, 33 ppm Zn, 49 ppm Pb

while others, which commonly display a minor amount of base metal enrichment, contain somewhat less silver and increased amounts of gold.

Sample 16829, 48 ppm Ag, 35.0 ppm Au, 1,190 ppm Cu, 1,230 ppm Zn, 36,000 ppm Pb Sample 16761, 30 ppm Ag, 12.6 ppm Au, 660 ppm Cu, 470 ppm Zn, 4,400 ppm Pb

The best area for gold mineralization appears to be located to the north of the old Homestake adit. Figure 10 shows those samples which ran greater than 1.0 ppm Au. Samples 17085 and 17086, located north of Twin Creek, contain over 1.0 ppm Au (Appendix 1). They were collected from a skarn horizon on a contact between Franklin Group sediment and rocks of the Averill Alkali Complex. The skarn contains small lenses of massive arsenopyrite.

Surface sampling and drilling by Longreach Resources identified a weakly mineralized, east-west oriented, shear zone cutting trachytic syenite (TS) on the Mapleleaf property (Figure 11). In outcrop, the zone consists of hematized and clay altered crushed syenite. The zone has been injected by a suite of now alterd "andesite" dykes. Quartz veins are relatively uncommon. The crushed syenite contains a trace of gold.

Sample 22031 2.7 ppm Ag, 0.15 ppm Au, 110 ppm Cu, 350 ppm Zn, 1850 ppm Pb

Several other mineral showings were identified in the vicinity of the Mapleleaf property. Most are quartz veins associated with east-west or north-south oriented faults.

4.5 Soil Geochemistry

A total of 5,134 conventional, B horizon, soil samples were collected on the property. The samples were collected at 40 metre stations throughout the Platinum Blonde grid. Sample density was increased to 20 metre stations in the vicinity of the Homestake, Banner and Bullion mineral showings. Samples were collected at an average depth of 20cm using a mattock. Most of the sample

material was found to be till or colluvium. Some samples collected in valley bottoms consisted of alluvial material

The samples were dried in the field and shipped to the Placer Dome Inc. laboratory in Vancouver. The minus 80 mesh fraction was sieved out and analyzed for Cu, Zn, Pb, Ni, Ag, Au, V and As. Most of the samples were also run for Pt and Pd. These elements were omitted over much of the area sampled at 20 metre intervals. These analytical data are included in Appendix 2(a).

Figures 12 (W,E) to 21 (W,E) show the point distibution of Cu, Zn, Pb, Ni, Ag, Au, V, As, Pt, and Pd.

Figures 12 (W,E) show that the earlier, more mafic, phases of the alkali complex display enrichment in copper. This is particularly noticeable in the vicinity of the Buffalo adit in the northwest corner of the Platinum Blonde grid. In this area the Cu content of the soil commonly reflects the nature of the underlying bedrock. High backgrounds are found over pyroxenite (Px), monzogabbro (MG), monzodiorite (MD) and monzonite (M). Trachytic (TS) and Coarse-grained syenite (cTS), which form a younger core to the intrusion complex are notably less enriched. Figures 15 and 18 (W,E) show that Ni and V display similar but weaker enrichment over the more mafic phases of the alkali complex.

Platinum and Palladium (Figures 20 and 21 (W,E)) values in the soil are generally low. Palladium does, however, show local enrichment in the vicinity of copper enriched pyroxenite near the Buffalo adit. Platinum and palladium occur as isolated, coincident, spot anomalies throughout the property. Most, but not all, are located over rocks belonging to the alkali complex. Some of the anomalies appear to be related to crush zones in the syenite complex.

Figures 16 and 17 (W,E) show the distribution of Ag and Au respectively. Both elements occur as isolated spot anomalies which are spread throughout the map area. They do not appear to correlate directly with any one lithology although both elements increase in value and extent of distribution over Franklin Group strata. This is particularly evident in the vicinity of the Homestake grid where anomalous values define "line segment" anomalies. Spot anomalies for gold were encountered over Kettle River and Marron Formation strata. Silver shows some enrichment in the vicinity of the Union vein.

Figures 13, 14 and 19 (W,E) show the distribution of Zn, Pb and As respectively. These elements are clearly

anomalous over Franklin Group strata south of Twin Creek. The three elements, along with gold and silver, are enriched in a series of overlapping line segments within a well defined area of apparant mineralization. The area is defined by Twin Creek in the north, the Banner and Bullion showings in the west, the Laura showing in the south and the Kettle River unconformity in the east. The various line segment anomalies show no simple correlation from line to line and it is difficult to project from one line segment to another. The pattern is probably a reflection of

both the wide range in direction displayed by the underlying vein system and the varied mineral content of the veins which host the mineralization.

Lead and zinc are found as rare spot anomalies elsewhere on the property. Arsenic is strongly developed on the north face of the Twin Creek drainage where it reflects the presence of massive arsenopyrite in skarn along the contact of the alkali complex.

The soil data appears to reflect the presence of two styles of mineralization in the Franklin Camp. The distribution of Cu in the northern part of the property appears to reflect the underlying presence of mafic phases of the Averill Alkali Complex and the distribution of Pb, Zn, Ag, (As, Au) largely reflects the presence of a variety of mineralized structures in rocks of the Franklin Group underlying the Kettle River unconformity.

A total of 96 bulk soil samples were collected from sites in the vicinity of the Buffalo showing in the northwest corner of the Platinum Blonde grid. The samples were collected in order to evaluate the significance of a weak positive correlation between Pt, Pd and Cu content observed in conventional soil samples previously collected in the same area. The samples consisted of 5.0-10.0 kg bags of B horizon soil. These were dried and shipped to Vancouver where the minus 150 mesh fraction was sieved out and sent to Bondar Clegg and Co. Ltd. for Pt and Pd analysis by fire assay and in DCP. Platinum and Palladium have detection limits of 15 and 2 ppb respectively. Analytical data are listed in Appendix 2(b) and posted in figures 22 and 23.

The data indicate that the distribution of Pt and Pd is closely tied to both the presence of pyroxenite (Px) and anomalous amount of copper.

4.6 Ground Geophysics

The geophysical surveys on the Platinum Blonde

property were carried out during the latter part of May, June and the first two weeks of July, 1987.

A VLF-EM survey was conducted using the transmitting station (NLK/24.8 kHz) at Jim Creek, Washington (near Seattle). Readings were taken facing 330° Az along the lines at 20 metre intervals as the direction to the station was 240° Az. The VLF-EM survey employed a Geonics EM-16 (ser. No. 25). VLF readings were entered onto floppy disk in a Kaypro I computer and field profiles of In-phase, Quadrature and Fraser Filter were plotted. The stored data was transferred to the Univac system for final plotting.

Magnetometer readings were taken at 10 metre stations and corrections for drift and diurnal changes were made by use of a base station recording magnetometer. The survey was conducted using two Geometrics G-856 A portable proton magnetometers (memory-mag). One was used in the field mode (Ser. No. 27503) while the other was used in a base station mode (Ser. No. 27502). The internal clocks were synchronized before commencement of the survey and subsequent daily readings were dumped out to floppy disk in a Kaypro I portable computer. The data from the two magnetometers were merged and corrected for diurnal drift from an established base station value. The corrected results were plotted as field profiles and also stored on disk for eventual transfer to a Univac 1108 mainframe for final plotting.

4.6.1 Magnetic Survey Results

The magnetometer survey results were plotted as plan maps of contoured data and stacked profiles at a scale of 1:5000 (Figures 24(W,E) to 26(W,E)).

Coarse trachytic syenite (cTs) is magnetically quiet in the west, however, trachytic syenite (Ts) is characterized by noisy magnetics similar to pyroxenite (Px) and monzodiorite (MD) (except for the area crossing the 63+00N Baseline at L40+00E where it has the same quiet response as trachytic syenite to the south-east).

The contact between Kettle River fanglomerate (Kf) and trachyte (T) is well defined in the east.

Hypidiomorphic diorite (D) appears to be somewhat magnetic on both of the fingerlike projections which intrude into Franklin Group sandstone (Fs) south of the 50+00N baseline and west of line 43+00E.

Minor dyke like responses were noted in the western

half of the property. These can be traced for 100 to 300 meters.

Trachytic sygnite (Ts) is characterized by a relatively quiet magnetic response on the east side of the east sheet, while on the west side it has a response similar to trachyte (T). Monzodiorite (MD) is quite active magnetically.

Kettle River Ka fanglomerate (Kf), arkose (Ka) and Franklin Group Strata (Fs/Fv) have a quite flat magnetic response and this distinction makes it relatively easy to trace the geologic boundaries between them and the more magnetically active plutonic rocks bordering them.

4.6.2 VLF Survey

The VLF-EM survey results were plotted as plan maps of stacked profiles of the In-phase, Quadrature and Filter data as well as contoured Fraser Filter data at scales of 1:5000 (Figures 27(W,E) to 30(W,E)). The Fraser Filter data was calculated as per the method put forth by D.C. Fraser (1969, Contouring of VLF-EM data, Geophysics v.34 p 958-967).

A study of the strike directions of the VLF conductor axes reveals that two prominent directions were detected by the VLF-EM survey. These azimuths are 062° and 088° with the following breakdown as listed:

					No. of Cond.
1)	062°	Az	- 054°	Az	21
			- 068°	Az	28
2)	088°	Az	- 080°	Az	33
1223			- 090°	Az	15
			- 100°	Az	21

Two minor strike directions of 027° Az (3) and 119° Az (4) were also detected.

Several of the conductor axes corresponded with mapped faults or geological contacts. Confirmation of some of the north-south faults can be shown by the termination of the east-west VLF conductors.

Interpreted conductor axes can be seen on Figures 27(W,E) and 28(W,E).

4.7 Diamond Drilling

Ten NQ diameter holes were drilled on the property for an aggregate length of 1,209 metres of core. The holes drilled in areas of known mineralization in the vicinity of the Averill (PDI 87-32), Laura (PDI 87-33 to 35), Jimmy (PDI 87-36 to 37), Mapleleaf (PDI 87-38 to 40), and Union (PDI 87-41) showings.

Drill hole details are listed in Table 2 and locations are shown on Figures 5 (W,E) 6 and 7.

The drill core was logged according to the computer based GEOLOG system of International Geosystems Ltd. The core was subsequently split and sampled according to geological criteria. Where possible samples consist of approximately three metres of similar material. The samples were shipped to the Placer Dome Inc. laboratory in Vancouver and they were analyzed for Cu, Zn, Pb, Ag, Au, As and, in some instances, Pt and Pd. Appendix 3 contains (1) an English translation of the GEOLOG drill log, (2) a graphic log and (3) analytical data.

The PDI drill program follows on from a similar program conducted by Longreach Resources Ltd. in December, 1986 and the core was logged according to the same conventions. For this reason the terms "Shonkinite" is used to refer to a hybridized monzodiorite or monzogabbro.

4.7.1 Averill Adit Area.

Hole PDI 87-32 was collared at locality L45+00E 56+00N on the Platinum Blonde grid immediately below and to the south of the adit portal. The hole was drilled at an angle of 50° on a bearing of 45°. It was collared to test for platinum and palladium bearing copper mineralization at depth below the adit and the trench system put in by Longreach Resources.

The hole encountered a mixed package of deformed plutonic rocks similar to those observed on surface. The core shows mixing of pyroxenite (Px) and syenite (S) and the development of a large amount of hybrid monzodiorite (MD) and monzogabbro (MG). The section shows that coarse syenite (cTS) becomes relatively abundant at the bottom of the hole. The syenite is locally highly deformed and intensely altered. Some of the crush zones are intruded by dykes of quartz feldspar porphyry.

A small amount of chalcopyrite was encountered throughout the section but there is no sign of significant mineral development at depth under the adit. Platinum and palladium values are at or near the detection limit.

TABLE 2

DIAMOND DRILL HOLE SUMMARY

PLATINUM BLONDE GRID:

Hole #		Coordinates		Azimuth	Dip	Length (m)	
PDI	87-32	L45+00E	56+00N	45°	-50°	306.63	
PDI	87-33	L52+35E	38+35N	260°	-50°	90.22	
PDI	87-34	L52+35E	38+35N	260°	-70°	117.04	
PDI	87-35	L51+90E	38+58N	160°	-50°	105.45	
PDI	87-36	L44+07E	42+25N	270°	-50°	74.98	
PDI	87-37	L44+07E	42+26N	270°	-75°	53.95	

UNION GRID:

Hole #		Coordinat	es	Azimuth	Dip	Length (m)
PDI 87-	-38	L28+19E 1	5+62N	0°	-50°	187.75
PDI 87-	-39	L28+00E 1	6+00N	0°	-50°	90.22
PDI 87-	-40	L27+72E 1	3+61N	20°	-50°	90.22
PDI 87-	-41	L26+00E	9+60N	0°	-50°	95.40

4.7.2 Laura Trench Area

Holes PDI 87-33, 34 and 35 were collared to test the significance of silver rich mineralization encountered in a series of trenches located near the cross roads south of the Homestake showing. Trench and drill hole locations are shown in Figure 31. Holes PDI 87-33 and 34 were collared at locality L52+35 E38+35N on the Platinum Blonde Grid. They were directed at an azimuth of 260° and they were drilled with dips of 50° and 70° respectively.

Both holes intersected a package of andesitic to dacitic volcanic breccia (Fv:) near surface. This was found to be underlain by a complex unit consisting of fine to coarse clastic sediment. The unit is comprised of an intimately intermixed succession of cherts (Fac:), shales (Fa:), sandstones (Fs:) and pebble conglomerates (Fc). The package is deformed and it contains zones of weak to intense cataclastic brecciation. Breccias are best developed in sections of massive cherty sediment. There is little sign of the intense silicification observed in the overlying trenches. Most fractures are filled with calcite.

The holes failed to intersect the style of mineralization observed on surface but the analytical data in Appendix 3 show that trace amounts of As, Pb, Au and Ag are found at various intervals down each of the holes. One sample from 33.07 to 34.72 metres in hole PDI 87-34 ran 25 ppm Ag, 0.1 ppm Au and 1390 ppm As.

Hole PDI 87-35 was collared at L51+90E 38+58N on the Platinum Blonde grid to test the the principal trench in the Laura area from a different angle. The hole was drilled with a 50° dip on an azimuth of 160°. The hole encountered a similar package of volcanic and sedimentary rocks as was found in the preceding holes. The package included some sections of silicified cherty sediment but again failed to account for the extensive mineralization observed in the surface trench.

The analytical data for hole PDI 87-35 show similar levels of trace element enrichment as were encountered in the earlier holes.

4.7.3 Jimmy Adit Area

Holes PDI 87-36 and 37 were collared to test a narrow (1.0 - 2.0 metre) northwesterly trending quartz vein located near the Jimmy adit. The two holes were collared at the same site at L44+07E 42+25N on the Platinum Blonde grid. The holes were drilled at an azimuth of 270° at dips

of 50° and 75° respectively. The holes intersected a deformed package of fine clastic sediment. The package consisted of an upper unit comprised of cataclastically deformed and brecciated cherty sediment (Fac:) and a lower unit comprised of sheared black carbonaceous shale (Fa:). No significant quartz veins were encountered. The package is gossanous on surface and contains abundant fracture controlled pyrite.Analytical data for holes PDI 87-36 and 37 show that the stockwork pyrite in the cherty sediment near surface is weakly anomalous in As.

4.7.4 Mapleleaf Adit Area

Holes PDI 87-38 and 39 were drilled to test for the downward extension of gold mineralization previously identified in an east-west oriented fault zone on the Mapleleaf claim (Figure 11). Drilling by Longreach Resources in 1986 had intersected a thick section of crushed, oxidized and weakly mineralized trachytic syenite (TS). The two holes were drilled at an azimuth of 0° with dips of 50° from sites at L28+19E 15+62N and L28+00E 16+00N on the Mapleleaf grid. Hole PDI 87-38 was collared a fair way back from the fault and it intersected a considerable thickness of trachytic syenite (TS) before entering the fault zone at a depth of approximately 125 metres. Hole PDI 87-39 was collared closer to the fault and it intersected the crush zone almost immediately.

The fault zone consists of a thick section of crushed trachytic syenite cut by a series of altered "andesite" dykes. The zone is locally either silicified or cut by recognizeable veins of quartz. The more highly deformed sections contain an appreciable amount of disseminated pyrite.

Analytical data in Appendix 3 show that the more intense zones of silicification and pyritization contain elevated gold contents. A 36.58 metre section from 120.69 to 157.27 metres in hole PDI 87-38 averages 0.166 ppm Au. No high-grade gold mineralization was encountered.

Hole PDI 87-40 was collared to test for chalcopyrite bearing syenite beneath the main platinumpalladium showing on the Mapleleaf property. The hole was sited at L27+72E 13+61N on the Mapleleaf grid. It was drilled at an azimuth of 20° and dip of 50°. Figure 32 shows the location of the hole, the showing and the inferred locations of holes drilled by Longreach Resources. The hole was expected to encounter a tectonic sliver of mineralized syenite in hornfelsed Franklin Group

)

strata immediately adjacent to its contact with trachytic syenite. In fact, the hole encountered a thick package of unmineralized hornfelsed sedimentary and volcanic strata which must project under the trachytic syenite. The intrusion contact is presumed to dip at a shallow angle to the north.

4.7.5 Union Mine Area

Piezoseismic tests carried out by the Department of Geophysics and Astronomy at the University of British Columbia suggested that an off-set portion of the Union vein might be present under a thin cover of Kettle River arkose west of the main (north-south oriented) Mapleleaf fault.

Hole PDI 87-41 was collared to test for this extension to the Union vein. The hole was sited on Kettle River formation arkose at L26+00E 9+60N on the Mapleleaf grid. The hole was drilled due north at an angle of 50°.

The drill hole intersected Kettle River pebble conglomerate, arkose and siltstone to a depth of 61.10 metres. At this point the hole encountered the Mapleleaf fault which is inferred to dip at approximately 50° to the west. Below the fault the hole encountered Franklin Group strata equivalent to that found around the Union vein. The section consists of a mixed package of siltstones and cherts. The latter are locally silicified and brecciated. The Union vein was not located. Figure 33 is a schematic representation of the inferred structure of the Mapleleaf fault.

5.0 CONCLUSIONS

The exploration program carried out on the Platinum Blonde property was designed to assist in evaluating the extent and significance of the known platinum-palladium and gold-silver mineral occurrences and to detect additional mineralization.

The results show that the known platinum-palladium showings are confined to areas of copper mineralization within orperipheral to a multiphase alkali intrusion ("Averill Alkali Complex"). The best mineralization encountered to date is located in a tectonic sliver of relatively fresh, coarsegrained, trachytic syenite exposed on the Mapleleaf property. The platinum group metals are located in coarse blebs of interstitial chalcopyrite. Somewhat more dispersed mineralization occurs near the Averill adit. At this locality platinum group metals are associated with blebs of chalcopyrite (1) in

FIG. 33

PLATINUM BLONDE PROJECT DRILL HOLE SECTIONS

micro-veins of syenite, (2) on fracture surfaces and (3) as dissemination in altered pyroxenite envelopes adjacent to syenite micro-veins. Platinum and palladium soil anomalies were found to correlate with areas of copper enrichment over early intrusive phases of the alkali complex. There is a strong correlation with pyroxenite in the vicinity of the Buffalo adit. No mineralization of any significance has been encountered in the vicinity of the soil anomaly.

The quartz-vein hosted silver-gold, mineralization was found to be restricted to a well defined block of deformed Franklin Group strata located south of Twin Creek. The mineralization is controlled by a variety of faults and interconnected brittle fractures. Some of the veins project under the Kettle River unconformity which suggests that the Mt. Franklin area was the site of widespread epigenetic mineralization prior to erosion and subsequent deposition of a cover of graben-fill sediment.

Several of the known showings have been drilled by Longreach Resources Ltd. and Placer Dome Inc. The results, to date, have not been encouraging. The property is, however, large and the results of the current program suggest that there is still considerable potential for both Mapleleaf (Pt,Pd,Cu) and Union (Au,Ag) style mineralization.

7.0 STATEMENT OF QUALIFICATIONS

I, Robert H. Pinsent of 2335 West 13th Ave., Vancouver, British Columbia (V6K 2S5), do hereby certify that:

- I am a geologist employed by Placer Dome Inc. of 1500-1055 Dunsmuir Street, Vancouver, British Columbia (V7X 1P1).
- I am a geology graduate of the following universities:

Aberdeen University, B.Sc, Hon., (1968) University of Alberta, M.Sc. (1971) Durham University, PhD. (1975)

- I have been engaged in the practice of geology since graduation in 1968.
- 4. I have supervised and carried out the fieldwork, and interpreted the data from the exploration on the Platinum Blonde Property (latitude 49° 33'N longtitude 118° 22'W) in the Greenwood Mining District.

Respectfully submitted,

R.H. Rysent

R.H. Pinsent

I, Richard W. Cannon, of the City of Vancouver, Province of British Columbia, hereby certify as follows:

- I am a graduate of the University of British Columbia where I recieved a B.A. Sc. in Geological Engineering (Geophysics Option) in May 1966.
- I am a member of the Association of Professional Engineers of British Columbia and have been so since 1968. Registration No. 6742.
- I am a member of the Canadian Institute of Mining and Metallurgy, Society of Exploration Geophysicist, and B.C. Geophysical Society.
- I have practiced my profession since 1966.

R.W. Cannon, P. Eng.

V217 PT BLONDE SOIL GEOCHEMISTRY

Summary of data from file : soils.bulk

The internal header for this file has 5 records

Title and comments: V217 PT BLONDE SOIL GEOCHEMISTRY

Data grouped into 7 fields by the following format: (A8, 4r10.0, 2r10.2)

Character ID fields:

Coordinate fields: CHDX CHDY UTHX UTHY

Fumeric data fields: PT PD

Missing data indicated by MULL value 99999.0

A. Ke shoukonite fragments encased by syenite veine or dykes post-dating the shoukonite 128 snonkonite with reliest pyroxenite fragments with small amount (.1%) Kopar Veins. 130 Symite dyke, sharp, chilled, contacts. 87-32 Page 2 of 5

Small, sychite dyke with local deformation. Shatering and grain size reduction. along with breceistion Medium grained. Syenite dyke, encasing coloritie shoukovite graguents up to locm long Reddish brown trachyte or (pulaskite) dyke. Fine grained. with porphyritic 230 calcite and Seldspars up to 0.5 cm 214 Fault zone consisting of brecciated pyroxemite fragments in a cataclastic matrix. Calcite and K-spar veins carry small amounts of pyrite and chalco. 23. Strongly Solicited shear zone, with brecciation and pyrite, chalcoamounts brecciation and pyrite, chalco-pyrite mineralization. Pyrite. 224 Arabion break filled with catachisti gromenite 05 Fault zone with intense clay chlorite alteration. zone of intense chloritic alteration Thin the shoukanite. Increased within amount as k-spar and calcite values. Both vein types have associated pyrite and chalcopyrite mineralization. 242 consisting Soult zome. Cataclastic symmite crush or breckin zon S with hematized Statures. Pyroxenite body (inclusion). with k-spar and calciter veins (micro to lem) epidate alteration chlorite-Aug. 200

Hematized crush zone GRAPHIC LOG in symite. Gray, andesitic dyke, porphyrytic feldspars, chilled contacts. Small guartz voins with altered selvages. 72 Grey, andesitie dyke, with minor 96 calcite vains and hematite stain chilled contacts. Hematized, fault zone at symite, andesite contact. sheared, and strongly tized. DA 107 64 Ö Zone of potassic alteration Pyrite (vein ; disseminations) 5%. Traces of chalco pyrite. 110 × grained, indesitie dyke, fine grained, massive, with small amounts of pyrite and calcite microveins, with hematite stainning. Chilled contacts. stainning. 2205 116 120 122 124 Zone of potassic alteration Fractured, with jucreased within symite. Sulfide. Pyrite 126 and chalcopyrite blebs. Grey and exitic dyke , nematite orain 05 87-38 Page 2 of 3 128 Fracture surfaces.
