COMMODITIES
SEARCHED FOR: Copper,Gold
GEOLOGICAL
SUMMARY: Copper-gold mineralization occurs in north trending hematitic quartz breccia veins and stockwork zones to 15 metres wide. Host rocks are siliceous feldspar porphyry volcanics of Jurassic age. Gold values range up to 9.7 grams per tonne over 3 metres in trenches and 6.8 grams per tonne over 6.15 metres in drilling.

TABLE OF CONTENTS

LIST OF FIGURES

INTRODUCTION:

The Todd Creek property is situated on the eastern side of the Coast Range Mountains of British Columbia, within the Skeena Mining Division. The property was staked to cover several Cu-Au occurrences which were originally discovered by Newmont Mining Corp. in 1959. 1987 fieldwork included saw trenching and mapping the showings, regional mapping, silt and rock sampling, and diamond drilling on the South Zone.

HISTORY:

The South and North Zone showings on the property were originally discovered in 1959 by prospector's Ole Olsen and Fred Hasselberg, Jr., in the employ of Newmont Mining Corporation. Newmont conducted a limited trenching and drilling program on the zones in 1960 with inconclusive results.

On the South Zone, a zone of chalcopyrite-pyrite stringers and hematitic quartz breccias, Newmont drilled 5 randomly spotted packsack drill holes.

In 1969, the South Zone showing was staked for Kerr Addison Mines by Wilf Christians. Kerr Addison, who recorded no work on the property, subsequently transferred title to Christians, who in turn sold the claims to C.S. Powney. During 1970-72, several trenches were blasted and sampled. In 1981, J.R. Woodcock Consultants staked the North Zone and a large altered area further north. From 1981 to 1984, Woodcock and Riocanex conducted extensive geological and geochemical programs on their claims. In 1985, Woodcock dropped everything except two units, which they currently hold.

In 1986, Noranda Exploration Company Limited staked the TOC 1-10 to cover the known showings. The TOC 11 and 12 were added later in 1986 and the TOC 13-15 in 1987.

LOCATION AND ACCESS:

The Todd Creek property is located in the Skeena Mining Division, approximately 45 km NNE of Stewart, B. C. (Figure #1) Highway #37A to Stewart passes 10 km to the south of the property. The property covers most of the western side of the Todd Creek valley and portions of Todd Creek glacier. Access to the property is via helicopter from Stewart, B. C.

PHYSIOGRAPHY & VEGETATION:

The property lies on the eastern flank of the Coast Range Mountains. Relief in the area is great, from 2900 feet in the valley bottom to 6800 feet on the highest summit. Todd Creek glacier and several valley glaciers occupy portions of TOC 11 and 12. The sides of the valley have extensive areas of bedrock exposure which commonly forms steep rock faces and cliffs. The valley bottom has a thick cover of glacial outwash material. Vegetation on the property consists of young willow, poplar and alder in the valley bottom, grading up slope into local stands of fir, hemlock and spruce and higher up into alpine meadows and bare rock.

CLAIM STATISTICS:

The Todd Creek property consists of 12 modified grid claims (Figure #2), as listed below:

NAME	UNITS	RECORD #	EXPIRY DATE
TOC 3	20	5305	April 9, 1989
TOC 4	20	5306	April 9, 1989

REGIONAL GEOLOGY:

The area has been mapped as being largely underlain by Lower Jurassic age Unuk River Formation volcanics and clastic sediments which are cut by numerous Jurassic and Tertiary age intrusive bodies ranging in size from narrow dykes and sills to large plutons. (Figure 3)

PROPERTY GEOLOGY:

South Zone

Geology - The South Zone is underlain by siliceous Feldspar Porphyry flows (?) which are exposed over an area 500m x 950m. (Figure 4) The porphyry flows are bounded to the west and north by dark green-grey andesite flows and agglomerate and to the south

SUMMARY:

The Todd Creek copper-gold property is located on the eastern flank of the Coast Range mountains approximately 45 km north northeast of Stewart, B. C. Mineralization, consisting of copper-gold bearing quartz and sulphide veins were first discovered by Newmont in 1959. Noranda staked the area of the showings in 1986 and has subsequently confirmed the presence of the copper-gold mineralization. To date, there are three main areas of interest:

1. South Zone: A copper-gold mineralized fracture zone cutting feldspar porphyry volcanics. Chip sampling on this zone in 1986 delineated an area 3m wide by 270m long, averaging 0.119 oz/T Au.

Drilling in 1987 tested the southern 175 meters of the zone. Significant intersections include 1.98 gmt Au/13.32 m (this includes 11.93 gmt Au/1.73 m), 4.10 gmt Au/2.0 m, 4.01 gmt Au/1.5 m, 3.51 gmt Au/1.38 m, 6.85 gmt Au/6.15 m, 2.84 gmt Au/9.93 m (includes 3.25 gmt/3.69 m and 3.36 gmt/2.61 m).

2. Mid Zone: A package of variably altered felsic volcanics mineralized with pyrite and minor malachite. Further prospecting and mapping located several new copper showings, but these contained no gold values. Soil/talus sampling over the northern part of the Mid Zone returned only local spotty values of little significance.

3. North Zone: Quartz breccia veins cut chloritic andesitic agglomerate. The best value from the North Zone trenches to date was 0.153 oz/T Au across 3m. A grab sample of old drill core, representing approximately 1 to 1.5 m, returned .58% Cu and .223 oz/T Au. Two of the North Zone veins were traced for over 250 meters to the south where they pinched out. Values ranged from .017 to .210 oz/T Au over 1 to 1.5 m widths.

The high grade breccia cobbles on the south side of Fall Creek were traced to the toe of a small glacier in central TOC 9 and it appears the source lies beneath the ice. A small soil grid on the south side of Fall Creek has outlined a copper-gold anomaly covering 200 m x 250 m. Values range up to 1030 ppm Cu and 360 ppb Au.

Reconnaissance silt, pan and rock sampling on the remainder of the property identified several streams which were anomalous in one or more of Au, Ag, As, Sb, Cu, Pb, Zn.

Further work is recommended on the three main areas as well as follow up on the stream and soil anomalies and continued reconnaissance work on the remainder of the property.

and east by glacial till. The western contact was not observed in outcrop, but is presumed to be a fault, while the northern contact is a sharply defined E-W trending, north dipping fault. The feldspar porphyry is pervasively altered; alteration ranging from quartz-pyrite, to quartz-sericite-pyrite, chlorite and iron-carbonate-quartz-sericite. The western 2/3 of the exposed porphyry body is predominantly quartz-pyrite altered and has a rusty yellow-brown weathered surface and is pale brown on a fresh surface. To the east, the porphyry is locally chloritic and proximal to the mineralized zone there is increased sericite alteration and locally iron-carbonate alteration. (Figure #6, 7, 8)

Mineralization - The mineralization, which consists of chalcopyrite, pyrite, specular hematite and malachite, is hosted in a 5 to 15m wide north-northeast trending, steeply west dipping fracture zone, which cuts the eastern flank of the exposed feldspar porphyry body. This zone has been traced for at least 900m. Mineralization occurs along the southern 425m and the northern 100m of the exposed portions of the zone. There are two types of mineralization within the fracture system:

1. massive pyrite-chalcopyrite stringers and veins from less than 1cm to 10cm wide, and,

2. a zone of quartz-hematite-chalcopyrite stringers and breccia veins to 3m wide.

Typically the zone consists of one or two larger quartz breccia veins separated by a stockwork of narrow quartz-hematite veins. The larger quartz breccia veins occur along the footwall and hanging wall of the zone. Above the main zone, moving into the hanging wall, is a zone of silica-sericite-chlorite alteration with minor quartz-hematite and/or pyrite +/- hematite stringers. The amount of pyrite veining was observed to increase from south to north.

Geochemically, the two types of mineralization are distinct; the pyrite-chalcopyrite veins generally have distinctly higher Mo, Cu and As values and lower Au values than the quartz breccia veins.

Prospecting to the west of the above mentioned zone revealed several local, narrow, quartz-chalcopyrite veins. These do not appear to have much significance. As well, silt samples collected in the western area did not define any new anomalous areas.

Trenching - A total of 11 saw trenches were completed on the south end of the South Zone. The trenches were cut using a Stihl TS350 rock saw equipped with a diamond blade. Two parallel cuts, 5cm deep and 2.5-4 cm apart, were made and the sample material was then chipped out with a chisel and hammer. Table 1 lists the significant trench results.

Drilling - A total of 9 drill holes, 1904 feet, were completed in 1987. The drilling was contracted out to Van Alphen Exploration Services, Smithers, B.C.

Drilling has confirmed that the mineralized zone continues to depth and has a fairly uniform westerly dip of 60-75 degrees. (Figures 11-15). The mineralized zone almost always consists of a footwall and hanging wall quartz-hematite breccia vein with a stockwork zone of quartz-hematite veins between. The hanging wall is marked by a zone, of variable width, of silica-chlorite-sericite alteration with varying amounts of quartz-hematite and/or pyrite-hematite veining. As indicated by surface mapping pyrite content increases from south to north. Flow banding observed in the drill core appears to confirm that the host rocks are indeed volcanic in origin. Table 2 lists the significant drill results.

Mid Zone

Geology - The Mid Zone is roughly located from the northwest corner of TOC 10 to the northern boundary of TOC 9. During 1987, the ridge from the northwest corner of TOC 10 to the south side of the icefield in central TOC 9 was extensively prospected (Figure 4, 5). The area is predominantly underlain by northtrending andesitic flows and agglomerate with minor interbedded feldspar porphyry flows and tuff, rhyolite flows, tuffs and volcaniclastics. As well there are two irregular feldspar porphyry bodies similar to the South Zone. The rhyolite and feldspar porphyry bodies are locally intensely quartz-sericite-pyrite altered.

Mineralization - Mineralization consists predominantly of east-west to northwest trending quartz-pyrite +/- chalcopyrite veins. The veins range from 1cm to 6m wide and 1m to 100m long. No significant precious metal values have been obtained from these veins. As well, there are local small zones and widespread large boulders of pyritic rhyolite breccia. This unit commonly contains 10-20% coarse grained pyrite with trace amounts of malachite. No significant precious metals were obtained from these rocks.

Silt samples collected from creeks draining the area were slightly anomalous in Cu, As, Co, Fe and Au.

Table 3 lists the sample results.

Grid Sampling - A small grid, the Ridge Grid, was established for the purpose of talus and/or soil sampling (Figure 9). Grid lines were established using a compass and hip chain. Samples were collected at 25 meter intervals along the grid lines with the use of a grub hoe. Sample material consisted of talus fines. The samples were place in "wet strength" kraft envelopes and shipped to Noranda Labs in Vancouver. The talus samples were then crushed and then all samples were screened and sieved to -80 mesh. For the analytical procedure, refer to Appendix III. A total of 102 talus samples were collected on the grid. Samples from the Ridge Grid returned local spot anomalies of little significance.

North Zone

Geology - Reconnaissance mapping and prospecting has been completed over only a limited area. Rock units identified are mainly andesitic agglomerates and flows and feldspar porphyry. The feldspar porphyry at the eastern end of TOC 8 appears to be an intrusive. The feldspar porphyry mapped in central TOC 8 and 9, however, is difficult to ascertain as to whether it is intrusive or is a flow rock. Detailed mapping of this area is required before any conclusions can be made. The feldspar porphyries and the andesitic volcanics to the west have been locally altered; predominantly to either quartz-sericite-pyrite or iron-carbonate-quartz-sericite. A broad north-south trending zone of patchy to pervasive alteration occurs in the north-central portion of TOC 9 and parts of TOC 8. This zone is on strike with the gossan north of the Mid Zone, which in turn appears to be continuous with the Mid Zone. As well, local areas in the andesitic agglomerates are weakly sericite altered and foliated and contain up to 10% disseminated pyrite.

Mineralization - Mineralization observed to date occurs in two areas:

1. the east-southeast portion of TOC 8, (A and B zones),

2. south-central TOC 8 and northwest TOC 9.

The eastern mineralization consists mainly of north-northwest trending, .1 to 2 meter wide hematitic quartz-chalcopyrite veins and vein breccias. These veins constitute what Newmont called the "A" and "B" zones.

In 1987 the veins on the north side of Fall Creek were partially resampled (Figure 11) and the southern extension of these veins were traced out and locally sampled (Figure 5). As well, a sample of old drill core, representing 1 to 1.5 meters of mineralized quartz vein, was collected. This sample returned .223 oz/T Au confirming that Newmont's drilling hit higher grade mineralization at depth than what is present at surface.

The "A" zone veins are hosted by dark green, chloritic andesitic agglomerate. On the north side of Fall Creek, the footwall of the veins has been intensely iron-carbonate-quartz +/- pyrite altered. This footwall alteration is 10-15 meters wide and the veins do not appear to enter it. The veins range from .1 to 2 meters wide and were traced for over 150 meters to the south of Fall Creek where the veins pinched to <10 cm wide and/or splayed out in several small veins.

In 1987, the area on the south side of Fall Creek, along and between 1st and Ice creeks, was further prospected in an attempt to find the source of the high grade float discovered in 1986. In 1987, the float was followed south to just below an icefield in central TOC 9. It is in the author's opinion that the source of the high grade float is beneath this icefield. In the process of prospecting, several new copper occurrences were located, but they did not contain any significant precious metal values. Table 4 lists the results of sampling.

Grid Sampling - As a follow up on 1986 silt samples 15151-57, two lines of soil samples, line 9800N and 10,000N, were completed over the source area.

The grid lines were established using a compass and hip chain and soil samples were collected from the B horizon with the use of

a grub hoe. Samples were placed in Kraft "wet-strength" envelopes and shipped to Noranda Labs in Vancouver where they were dried and sieved to -80 mesh. Refer to Appendix III for analytical procedure.

The sampling outlined a strong coincident copper-gold anomaly 200m x 250m and open to the north and south. Values range up to 1030 ppm Cu and 360 ppb Au. This area warrants further sampling and trenching.

Virginia Creek

Recon Sampling - A total of 2 days were spent stream sampling and prospecting in the Virginia Creek valley. A total of 12 heavy mineral (pan) samples, 16 silt samples and 3 rock samples were collected. (Figure 17) Table 5 lists the sample results.

80998	silt	1	20	18	115	.5	18	2	1

The sampling has indicated two moderately anomalous areas, one on the north side and one on the south side of Virginia Creek. The anomaly on the north side of the creek consists of 3 sample sites, samples 80956-7, 80965-8, with anomalous values in Pb, Ag, As +/- Zn. The anomaly on the south side of the creek consists of 5 sample sites, samples 80958-62, 80971-5, 80991-2, with anomalous values in Au, Ag, As, Sb, Pb, Zn. Of particular note are stream samples 80971-2 and rock samples 80973-5. The 3 rock samples consisted of andesitic volcanic breccia containing 3-5% pyrite and .5-1% arsenopyrite. This area definitely warrants further sampling and prospecting.

TOC 12

Recon Sampling - During 1987, a large rusty, altered area was prospected and a total of 8 rock/talus samples were collected. (Figure 18) Table 6 lists the sample results.

TABLE 6: TOC 12 SAMPLE RESULTS

(all values in ppm except where noted)

SAMPLE	TYPE	Mo	Cu	Pb	Zn	Ag	As	Sb	Au (ppb)
85187	rock	3	29	98	3	1.0	127	9	2
85188	talus	3	18	33	86	.2	16	2	1
85189	rock	7	35	140	5	2.8	118	13	21
85190	talus	2	11	22	51	.2	10	2	1
85191	rock	184	36	30	19	1.5	213	5	17
85192	rock	2	38	14	13	.4	7	4	2
85193	talus	1	39	25	97	.2	6	2	1
85194	talus	1	37	22	102	.1	11	4	1

The gossan proved to be a north-northwest trending zone of quartz-sericite-pyrite altered rhyolite tuffs which are bounded by maroon-green andesitic volcanics. The tuffs contains local vuggy siliceous zones with 10-15% pyrite. No significant precious metals were obtained from this area.

Knob Zone (TOC 15)

Recon Sampling - The Knob Zone is a prominent gossanous ridge which rises from the bottom of the Todd Creek valley. (Figure 19) The northern end of the ridge is composed of a tan-brown siliceous hornblende-feldspar porphyry (possibly trachyte?). Feldspar phenocrysts range up to 1cm in size. Mineralization consists of discontinuous zones to 5 meters wide of intense quartz-sericite-pyrite alteration which contain 1-25cm wide massive pyrite seams. The number and intensity of the alteration zones appears to decrease to the south. To the south, on the east side of the Knob Zone ridge, several 1-10cm wide chalcopyrite veins were also located. Table 7 lists the sample results.

TABLE 7: KNOB ZONE ROCK SAMPLE RESULTS

(all values in ppm except where noted)

SAMPLE	TYPE	Mo	Cu	Pb	Zn	Ag	As	Sb	Au (ppb)
80976	py vein	5	13	107	93	1.7	329	2	41
80977	py vein	5	32	16	9	.3	232	2	25
80978	py vein	5	14	95	267	1.1	578	2	119
80979	py vein	2	3	4	5	.5	135	2	13
80980	py vein	7	52	233	52	1.5	975	2	71
80981	py vein	3	18	19	6	.3	236	2	7
80982	jasp-hem	95	3	15	28	.1	29	39	1
80983	cpy vein	12	734	62	104	1.3	529	2	111
80984	cpy vein	2	3697	13	207	1.4	203	210	5
80985	py vein	2	7	15	10	.2	286	2	10
80986	py vein	30	236	25	16	.8	584	2	126
86769	py vein	3	89	52	107	.5	811	2	108
86770	py vein	3	49	114	37	.4	455	2	530
86771	py vein	1	52	27	20	.7	770	3	270
86772	py vein	4	14	16	12	2.2	177	2	121
86773	py vein	6	13	13	9	1.4	100	3	37
86774	py vein	5	9	20	16	1.5	267	2	47
86775	py vein	5	9	35	25	.3	328	2	40

The sample results indicate that the pyrite veins are weakly auriferous but do not contain economic concentrations of gold.

BY Glacier (TOC 10)

Recon Sampling - The BY glacier lies immediately southwest of the South Zone camp and runs east-west. A one day recon traverse along the north side of the glacier (Figure 4) was completed. A total of 6 rock/talus samples were collected. Table 8 lists the sample results.

TABLE 8:

(all values in ppm except where noted)

SAMPLE	TYPE	Mo	Cu	Pb	Zn	Ag	As	Sb	Au (ppb)
85181	rock	16	13	10	37	.1	29	14	5
85182	rock	3	29	15	18	.5	95	61	8
85183	rock	9	552	15	19	.3	44	16	1
85184	talus	4	23	35	183	.4	21	3	2
85185	talus	5	11	35	107	.1	13	5	1
85186	talus	1	16	28	150	.2	9	3	1

Due to the steep terrane, only the slope immediately above the glacier could be prospected. This slope was usually covered by considerable talus material. This talus material, from sample site 85181 to 85183, consists mainly of felsic volcanics. These volcanics appear to range from dacite flows and fragmentals to rhyolite. Local rhyolite float was observed to have a heavy limonite +/- hematite coating. Several pieces were also found to

be vuggy with pyrite in the vugs. These felsic rocks appear to be a southern continuation of the felsic package identified in the Mid Zone.

Todd Creek Valley

Recon Sampling - Pan and silt sampling along the main Todd Creek Valley has identified several anomalous areas on both sides of the valley. (Figures 4, 5) The anomalies on the east side of the valley are predominantly Pb +/- As-Zn-Au. The anomalies on the west side are predominantly Cu-Au +/- Pb-As. This difference probably reflects two different geologic environments.

CONCLUSIONS:

Work completed in 1987 has outlined several target areas which warrant further work. These are:

1. South Zone - drilling has confirmed the presence of significant gold values over appreciable widths (up to 6.85 gmt Au/6.15m) within the South Zone. The erratic nature of the gold distribution in the drill holes may be due to the presence of higher grade shoots within the zone. Trenching across the wide stringer zone at the southern end returned generally sub-economic gold values.

2. Mid Zone - mapping and sampling have failed to outline any significant mineral zones. The zone of felsic volcanics previously identified now appears to be continuous to the south at least to the BY glacier. To date however, no significant mineralization has been found associated with these volcanics.

3. North Zone - follow up of the high grade float material indicates that the source lies under a small icefield in central TOC 9. Soil sampling on the south side of Fall Creek has outlined a strong coincident copper-gold anomaly 200m x 250m. Values range up to 1030 ppm Cu and 360 ppb Au. Resampling of the "A" zone trenches again returned low gold values but a sample of old core representing 1 to 1.5m of mineralized quartz vein returned .223 oz/T Au and .58% Cu. This confirms the presence, at least locally of significant gold values at depth.

4. Virginia Creek - reconnaissance stream and rock sampling has outlined two multi-element anomalous areas, one on each side of the creek. Rock samples from the area of the southern anomaly have returned values to 9.1 ppm Ag, 5530 ppm As, 73 ppm Sb and 175 ppb Au.

5. TOC 12 - reconnaissance prospecting and sampling failed to locate any significant mineralization. This work covered a large gossan in central TOC 12.

6. Knob Zone (TOC 15) - a large, prominent gossan with extensive areas of intense quartz-sericite-pyrite alteration was thoroughly prospected and sampled. Rock sampling indicates that the altered areas are only weakly anomalous in gold, best value 530 ppb.

7. BY Glacier (TOC 10) - reconnaissance work indicates that the felsic volcanics identified in the Mid Zone continue at least as far south as the BY glacier. No significant mineralization was located in this area to date.

RECOMMENDATIONS:

1. South Zone - continued drill testing. This should include holes to the north of NTC-8, 9 and another hole beneath each of NTC-3, 5, 7 and 9.

2. Mid Zone - further prospecting to the east along the creeks draining the Mid Zone.

3. North Zone - drill test the "A" zone, enlarge the grid covering the copper-gold soil anomaly for the purpose of mapping sampling and trenching.

4. Virginia Creek - follow up the 1987 anomalies with further sampling and prospecting.

5. TOC 12 - no further work is recommended in this area at this time.

6. Knob Zone (TOC 15) - no further work is recommended in this area at this time.

7. BY Glacier (TOC 10) - further prospecting and reconnaissance soil and rock sampling along the north side of the glacier.

8. Todd Creek Valley - follow up anomalous silt-pan samples with further sampling and prospecting.

APPENDIX II

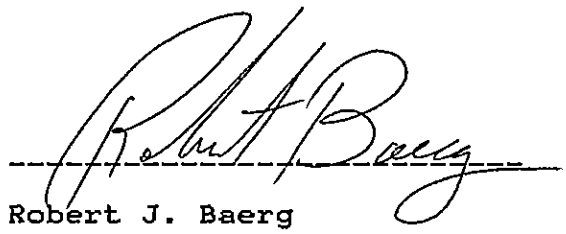
STATEMENT OF QUALIFICATIONS

I, Robert J. Baerg of the City of Prince George, Province of British Columbia, do certify that:

1. I have been employed as a geologist by Noranda Exploration Company, Limited since May, 1984.

2. I am a graduate of the University of British Columbia with a Bachelor of Science (Honors) in Geology (1984).

3. I supervised and assisted with the work described in this report.



Robert J. Baerg
Geologist
Noranda Exploration Company, Limited
(No Personal Liability)

APPENDIX III

ANALYTIGAL PROCEDURES

The methods listed are presently applied to analyse geological materials by the Noranda Geochemical Laboratory at Vancouver. (March, 1984).

PREPARATION OF SAMPLES

Sediments and soils are dried at approximately 80°C and sieved with a 80 mesh nylon screen. The -80 mesh (0.18 mm) fraction is used for analysis.

Rock specimens are pulverized to -120 mesh (0.13 mm). Heavy mineral fractions (panned samples) are analysed in its entirety, when it is to be determined for gold without further sample preparation.

ANALYSIS OF SAMPLES

Decomposition of a 0.200 g sample is done with concentrated perchloric and nitric acid (3:1), digested for 5 hours at reflux temperature. Pulps of rock or core are weighted out at 0.2 g or less depending on the matrix of the rock, and twice as much acid is used for decomposition that that is used for silt or soil.

The concentrations of Ag, Cd, Co, Cu, Fe, Mn, Mo, Ni, Pb, V and Zn (all the group A elements of the fee schedule) can be determined directly from the digest (dissolution) with an atomic absorption spectrometer (AA). A Varian-Techtron Model AA-5 or Model AA-475 is used to measure elemental concentrations.

ELEMENTS REQUIRING SPECIFIC DECOMPOSITION METHOD

Antimony - Sb: 0.2 g sample is attached with 3.3 ml of 6% tartaric aid, 1.5 ml conc. hydrochloric acid and 0.5 ml of conc. nitric acid, then heated in a water bath for 3 hours at 95°C. Sb is determined directly from the acid solution with an AA-475, equipped with electrodeless discharge lamp (EDL).

Arsenic - As: 0.2 - 0.4 g sample is digested with 1.5 ml of 70% perchloric acid and 0.5 ml of conc. nitric acid. A Varian AA-475 equipped with an As-EDL measures the arsenic concentration of the digest.

Barium - Ba: 0.1 g sample is decomposed with conc. perchloric, nitric and hydrofluoric acid. Atomic absorption using a nitrous oxide-acetylene flame determines Ba from the aqueous solution.

Bismuth - Bi: 0.2 g - 0.3 g is digested with 2.0 ml of perchloric 70% and 1.0 ml of conc. nitric acid. Bismuth is determined directly from the digest into the flame of the AA instrument c/w EDL.

Gold - Au: 10.0 g sample sample (Pan-concentrates see below) is digested with aqua regia (1 part nitric and 3 parts hydrochloric acid). Gold is extracted with Methyl iso-Butyl ketone (MIBK) from tje aqueous solution. Gold is determined from the MIBK solution with flame AA.

Magnesium - Mg: 0.05 - 0.10 g sample is digested with 4 ml perchloric/nitric acid (3:1). An aliquot is taken to reduce the concentration to within the range of atomic absorption. The AA-475 with a nitrous oxide flame determines Mg from the aqueous solution.

Tungsten - W: 1.0 g sample sintered with a carbonate flux and thereafter leached with water. The leachate is treated with potassium thiocyanate. The yellow tungsten thiocyanate is extracted into tri-n-butyl phosphate. This permits colourimetric comparison with standards to measure tungsten concentration.

Uranium - U: An aliquot, taken from a perchloric-nitric (3:1) decomposition, usually from the multi-element digestion, is diluted with water and a phosphate buffer. This solution is exposed to laser light, and the luminescence of the uranyl ion is quantitatively measured on the UA-3 (Scintrex).

LOWEST VALUES REPORTED IN PPM

Ag - 0.2	Mn - 20	Zn - 1	Au - 0.01 (10 ppb)
Cd - 0.2	Mo - 1	Sb - 1	W - 2
Co - 1	Ni - 1	As - 1	U - 0.1
Cu - 1	Pb - 1	Ba - 10	
Fe - 100	V - 10	Bi - 1

ASSAY REQUIRED FOR Cu > 10,000 ppm
Zn > 20,000 ppm
Ag > 35 ppm

ACME ANALYTICAL LABORATORIES 852 E. HASTINGS ST. VANCOUVER B.C. V6A 1R6 PHONE 253-3158 DATA LINE 251-1011

GEOCHEMICAL ICP ANALYSIS

.500 GRAM SAMPLE IS DIGESTED WITH 3ML 3-1-2 HCL-HNO3-H2O AT 95 DEG.C FOR ONE HOUR AND IS DILUTED TO 10 ML WITH WATER.
THIS LEACH IS PARTIAL FOR MN FE CA P LA CR MG BA TI B W AND LIMITED FOR NA AND K. AU DETECTION LIMIT BY ICP IS 3 PPM.
- SAMPLE TYPE: P1-SILT P2 TO P4-TALUS P5-ROCK AU* ANALYSIS BY AA FROM 10 GRAM SAMPLE.

DATE RECEIVED: AUG 21 1987 DATE REPORT MAILED: Aug 31/87 ASSAYER. D. Toye...DEAN TOYE, CERTIFIED B.C. ASSAYER

ASSAY REQUIRED FOR Cu > 10,000 PPM.

Mid. Zone

← Massive Sulphide type geochem

Central Cord District

20 Rx
5 Pans
7 Silts
102 Talus

Rx+ Silts + Talus: ICP + Au
Rx: (Assay Cu, Au) (Assay Pb, Zn, Ag, Au) + ICP
All to Acme
PAN: BM, Au

Sheet 1 of 4

Lab Code 8708-090

RECORD OF SAMPLE TRANSMITTAL

NORANDA EXPLORATION COMPANY, LIMITED
P.O. BOX 2380
1050 DAVIE STREET
VANCOUVER, B.C.
V6B 3T5

(P) 24/08

N.B. Partial results (silt & 7 Au's) mailed 27/08 to P.G.

Date Shipped:
Date Received: Aug 17/87
Shipped Via: Bus
No. of Cartons:
No. of Samples: 46
Geologist: R. Baerg
Date: Aug 9/87

MATERIAL:
- [ ] SOIL
- [x] SILT
- [x] ROCK
- [x] Pan

LEGEND

ROCK TYPES

1 — Hornblende-Feldspar Porphyry Volcanic
1-2mm euhedral hornblende and feldspar grains in a green or pale to medium brown aphanitic matrix, local aphanitic and banded tuff fragments, local tuff-volcanic breccia.

1c — quartz +/- pyrite altered, white to pale brown weathering.

1b — sericite +/- quartz-pyrite altered, rusty yellow weathering.

1c — chlorite +/- quartz-epidote-pyrite altered, white to pale green weathering.

1d — carbonate +/- quartz-pyrite-epidote altered, pale to dark brown weathering.

2 — Andesite, anhedral feldspar grains in a maroon to dark grey matrix, 2-5% disseminated specular hematite grains, local 1-2mm pale grey fragments, minor carbonate.

2d — carbonate +/- pyrite altered, dark brown weathering.

Quartz-hematite-chalcopyrite +/- chlorite +/- calcite vein and/or intense stockwork.

Quartz-hematite-chalcopyrite +/- chlorite +/- calcite stringer zone, veins to 20cm wide.

Pyrite-sericite-chalcopyrite vein zone, massive veins to 20cm wide.

Pyrite-sericite-chalcopyrite stringer zone, veins to 5cm wide, widely spaced.

qtz - quartz
hem - hematite
cpy - chalcopyrite
chl - chlorite
ep - epidote
cc - calcite
py - pyrite
mal - malachite
rhy - rhyolite

ROCK TYPES

1	Hornblende-feldspar Porphyry Volcanic Hornblende-feldspar porphyry volcanic 1-2mm euhedral hornblende and feldspar grains in a green or pale to medium brown aphanitic matrix, local aphanitic and banded tuff fragments, local tuff-volcanic breccia.
1a	quartz +/- pyrite altered, white to pale brown weathering.
1b	sericite +/- quartz-pyrite altered, rusty yellow weathering.
1c	chlorite +/- quartz-epidote-pyrite altered, white to pale green weathering.
1d	carbonate +/- quartz-pyrite-epidote altered, pale to dark brown weathering.
2	Andesite, anhedral feldspar grains in a maroon to dark grey matrix, .2-.5% disseminated specular hematite grains, local 1-2mm pale grey fragments, minor carbonate.
2d	carbonate +/- pyrite altered, dark brown weathering.
	Quartz-hematite-chalcopyrite +/- chlorite +/- calcite vein and/or intense stockwork.
	Quartz-hematite-chalcopyrite +/- chlorite +/- calcite stringer zone, veins to 20cm wide.
	Pyrite-sericite-chalcopyrite vein zone, massive veins to 20cm wide.
	Pyrite-sericite-chalcopyrite stringer zone, veins to 5cm wide, widely spaced.

ROCK TYPES

1 — **Feldspar** Porphyry, pale brown, Ia-quartz-pyrite altered, Ib-quartz-sericite pyrite altered, Ic-chlorite altered, Id-iron-carbonate +/- quartz-sericite altered.

2 — Dark green, maroon, grey andesite flows, agglomerate tuff, breccia

3 — Light grey-green feldspar porphyry flows, tuff and tuff breccia

4 — Rhyolite, massive, breccia, lapilli tuff, locally quartz-sericite-pyrite altered

5 — Dark green hornblende porphyry intrusive

Quartz-pyrite +/- sericite altered mineralized zone
