CLAIM(S): Silver Hill

OPERATOR(S): Atna Res.

AUTHOR(S): Harivel, C.

REPORT YEAR: 1988, 28 Pages

COMMODITIES

SEARCHED FOR: Silver,Gold,Copper

GEOLOGICAL

SUMMARY: The property is underlain by red tuffaceous volcanics of the Lower Jurassic Hazelton Group. Three kilometres southwest, a large granodiorite stock of Upper Cretaceous age intrudes the volcanics. Lower Cretaceous sandstone rests unconformably on the volcanics. Major north-northeast trending faults cut across the claims. Early work reported the presence of electrum in an adit developed along a shear-hosted vein structure.

INTRODUCTION:

The claim was staked in late winter of 1987 as a result of library research. In July 1987 an assessment of the ground and geologic setting was made by Colin Harivel and Mary Lou Mallot. A camp was flown into the property on July 1 and in the course of the 5 day stay on the property, preliminary geologic mapping and soil sampling on wide-spaced lines was completed.

This report summarises some previous work done on the property and describes the work done in 1987.

LOCATION AND ACCESS:

The property is located about 45 km southwest of Smithers. The last few kilometers are along four-wheel drive road which, in early summer, may be difficult to negotiate in places. The route from Smithers is through the village of Telkwa, along Coalmine Road to Goathorn Creek turnoff and then along the road to Cabin Creek.

PHYSIOGRAPHY:

The property lies in the extreme north of the Telkwa Range within the Hazelton Mountains of the Bulkley Ranges. The property is sub-alpine and elevations range from 5100' (1555m) to 5700' (1737m) above sea level. The gentle upland surface which occupies the centre of the property is largely grass-covered. All drainage from the property is into tributaries of the Telkwa River which flows into the Bulkley River.

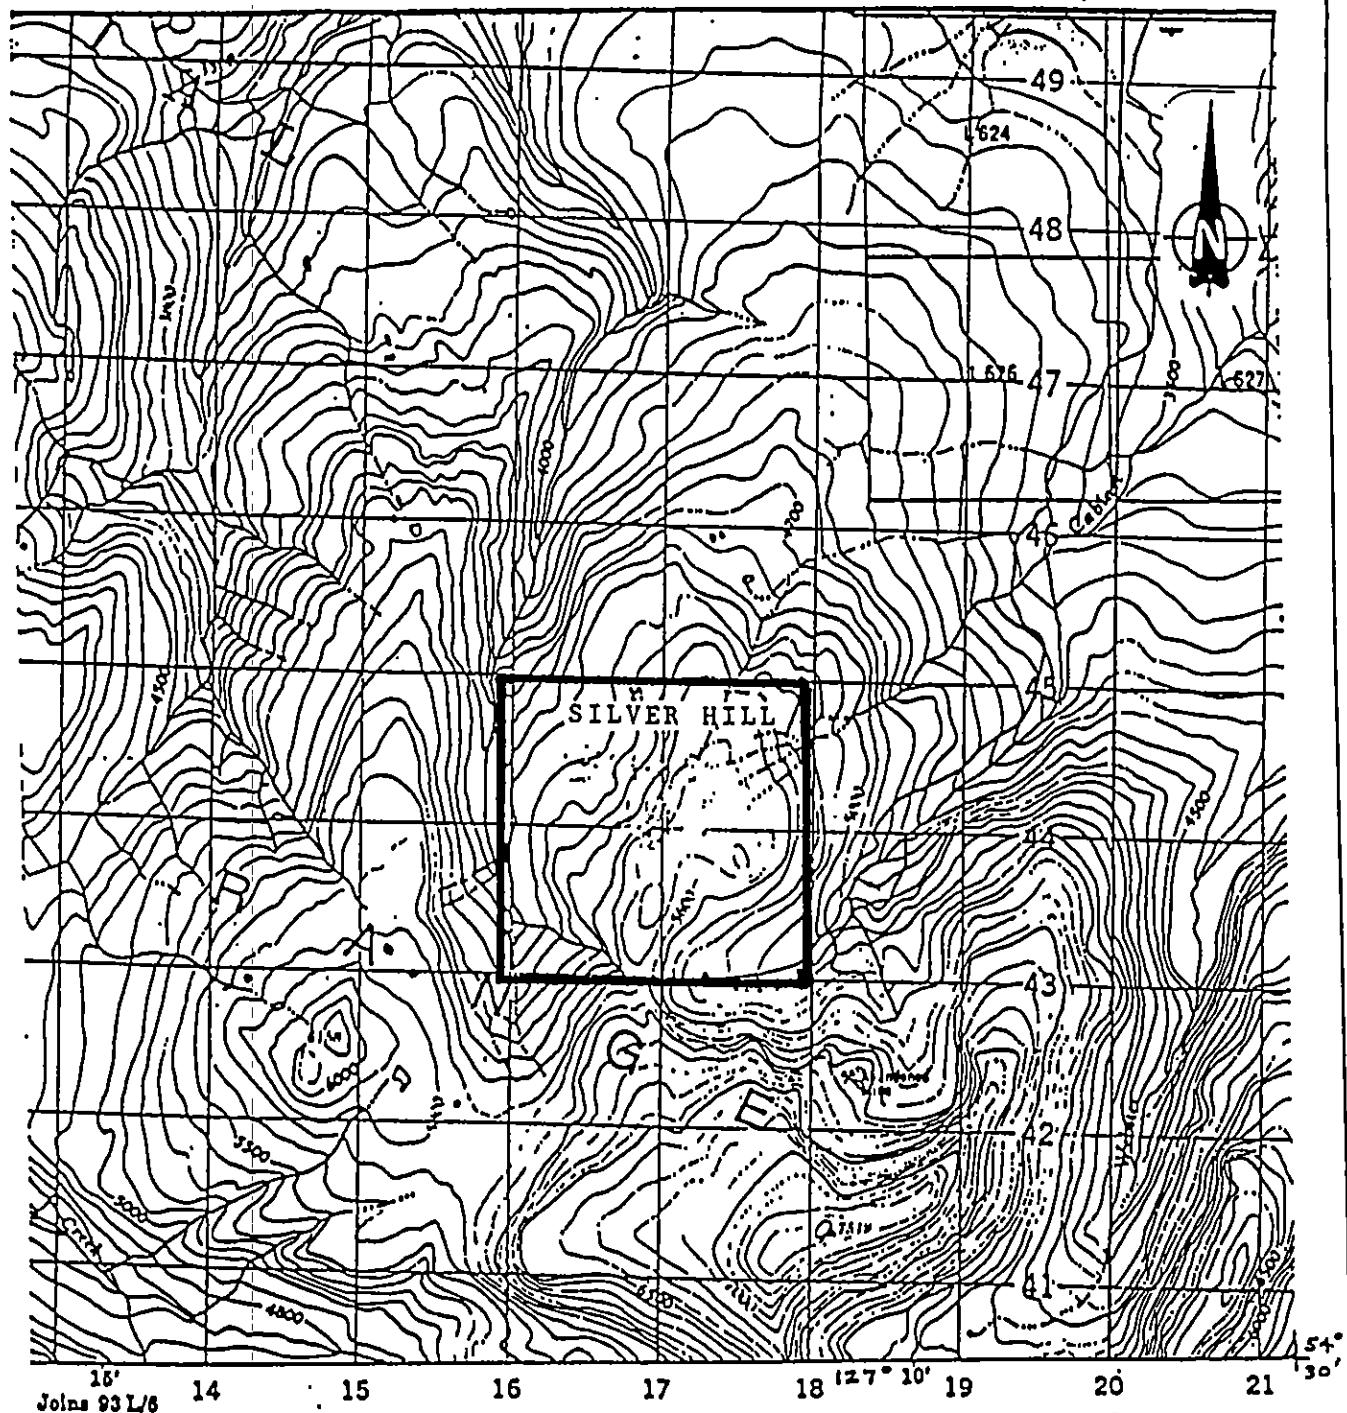

PROPERTY HISTORY:

The property was first discovered in 1909, with several tunnels and a shaft having apparently been developed, but no work of any significance has been done since 1915. The older workings have been buried by creep of the mobile felsenmeer cover. The location of the Colorado Adit is indicated by the conspicuous dump, but the portal has caved.

CLAIMS INFORMATION:

The property consists of the SILVER HILL mineral claim of 16 units (Figure 1). The record number is 8212 and the expiry date is March 13, 1989. The claim is owned by Atna Resources Ltd.

ECONOMIC ASSESSMENT:

The property is a volcanic-hosted, structurally controlled, precious metals target. Early work has demonstrated economic potential based on the reported presence of electrum in an adit developed along a shear-hosted vein structure. Recent geochemical soils analyses have demonstrated significant extensions and additions to the earlier known mineralized structures.

REGIONAL GEOLOGY:

The region is situated along the west-central part of the Stikine Terrane. Stratified and plutonic rocks range in age from Upper Paleozoic to Early Tertiary, with rocks of Jurassic age and younger being dominant.

Four major tectono-stratigraphic elements dominate the region:

The Lower and Middle Jurassic Hazelton Group comprises a marine and non-marine arc assemblage that is the preponderant rock assemblage in the area of interest. These strata are mainly non-marine rhyolitic to andesitic flows, pyroclastics and hypabyssal intrusives comprised of interfingering assemblages of flows, ignimbrites, lahars, air fall tuffs and breccias, volcaniclastic sediments and high level intrusive units. Consanguineous with the volcanics are diorite to granite plugs and stocks of the Topley Intrusions.

The interval between Upper Jurassic and Early Upper Cretaceous time is occupied by two sedimentary assemblages that appear to have little bearing on mineralization in this area.

To the immediate north of the area of interest, Upper Jurassic to mid-Lower Cretaceous Bowser Lake Group comprise a northwardly thickening wedge of deltaic-foredeep deposits. The source of the sediments was the Hazelton Group to the south and the depositional basin is known as the Bowser Basin. The locus of the strand lines across the southern limit of the Bowser Basin defines a structure known as the Skeena Arch, one of the most intensely mineralized belts in the Canadian Cordillera.

Between the mid-Lower Cretaceous and early Upper Cretaceous, the Skeena Group sediments were deposited across the entire region. This unit represents a continental margin clastic wedge, whose sediments were derived from the east, off the Omineca Terrane.

The late Upper Cretaceous to Eocene time is represented by a suite of continental transtensional arc volcanics that were deposited in an array of down-drop volcanic basins within the Stikine Terrane from latitude 55°30'N southward. These volcanics (the Kasalka and Ootsa Lake Groups) and their coeval intrusives

(Bulkley, Babine, Nanika) are associated with the development of basin and range geomorphology that typifies this segment of the Stikine Terrane.

Post-Eocene time was one of uplift, erosion and local deposition of basalt. It served to expose mineralization.

Early and Middle Jurassic age arc-related mineralization is widespread and precious-metals based. Included within this epoch is the Toodoggone gold silver camp, and the major deposits of Silbak-Premier, Big Missouri and Granduc along the east flank of the Coast Range. Mineralization in the Smithers-Whitesail area likely of this epoch includes the Dome Mountain deposits and those of the Topley-Richfield area.

Late Cretaceous - Early Tertiary aged mineralization in the Skeena Arch is presently the most varied, widespread and significant of the two epochs. All the copper, molybdenum, tungsten and gold-bearing porphyries belong to this stage. Precious metals properties include Equity Silver, New Nadina, Silver Standard, Cronin and a host of smaller properties. Most of these deposits are related to the evolution of down-drop basins and calderas associated with volcanism, related plutonism and the development of a basin-and-range geomorphology. These deposits range from low temperature epithermal to high temperature mesothermal types.

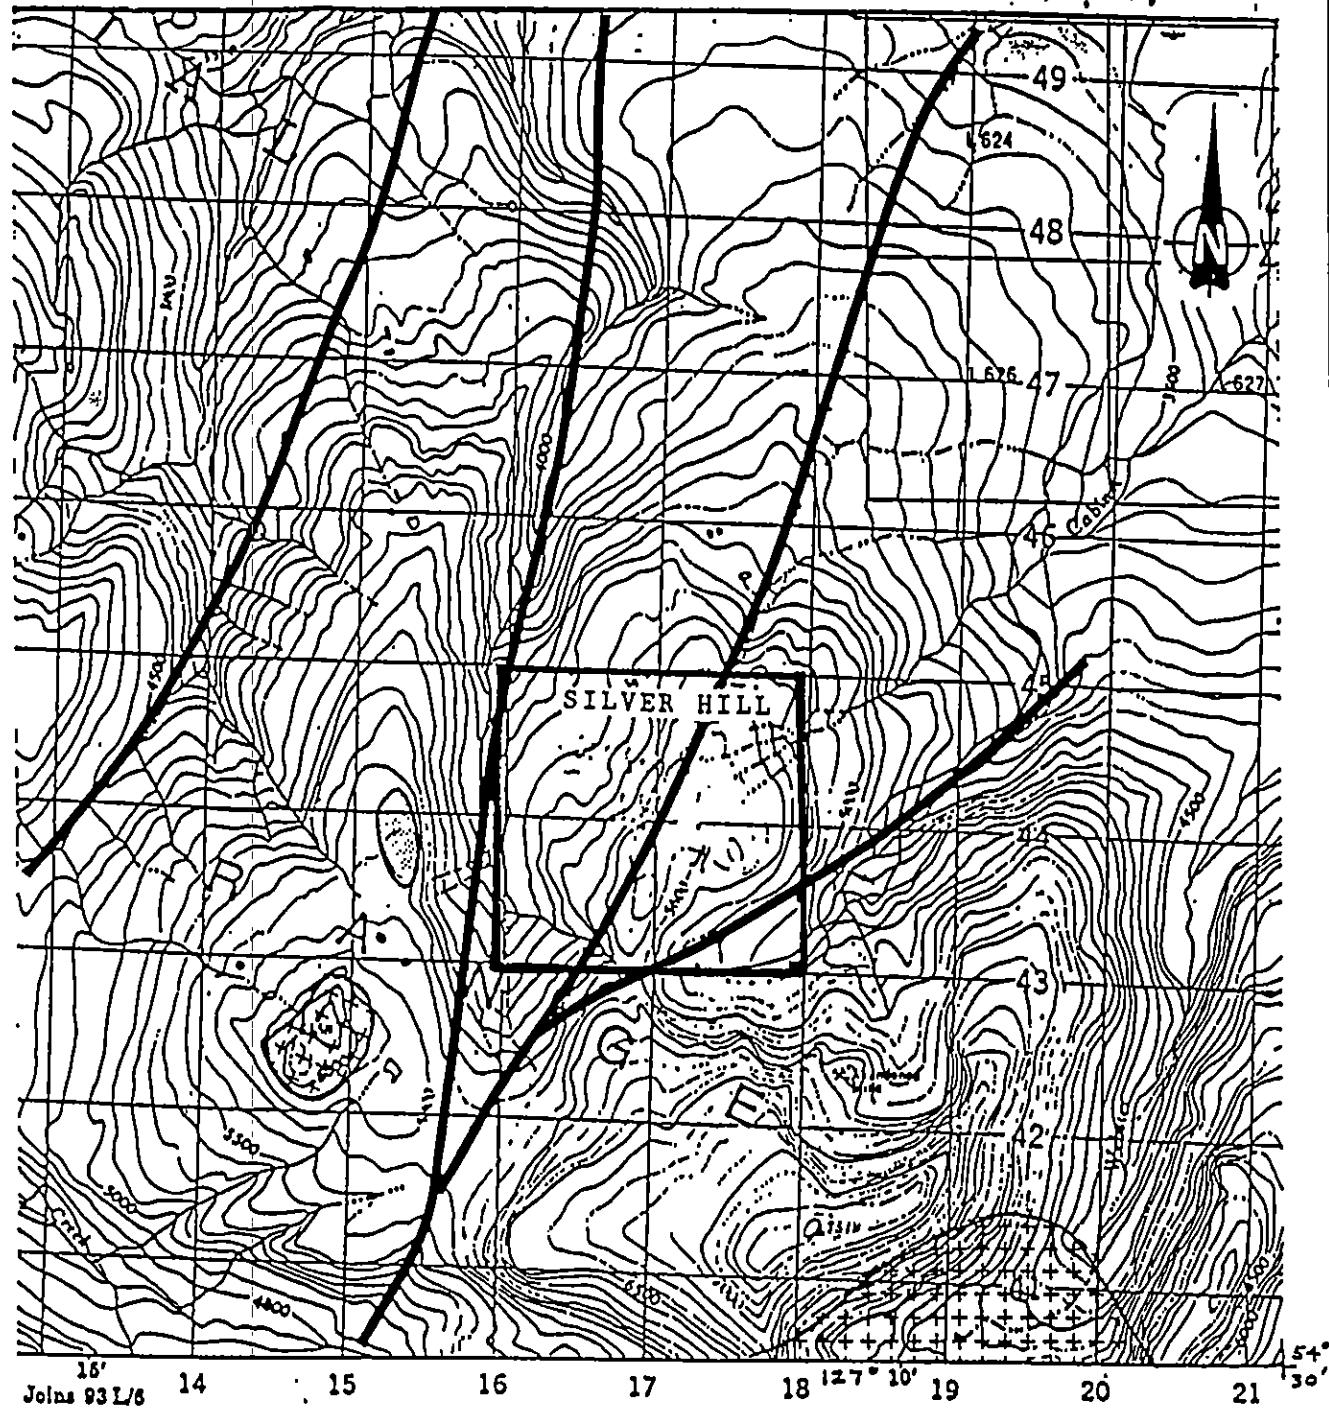

PROPERTY GEOLOGY:

The claims are underlain by red tuffaceous volcanics of the Lower Jurassic Hazelton Group (Figure 2). Three kilometers to the southwest, a large granodiorite stock of Upper Cretaceous age intrudes the volcanics and forms the core of the Telkwa Mountains. A small satellite stock or sill is exposed one kilometer to the southwest. A small outlier of Lower Cretaceous sandstone rests unconformably on Hazelton volcanics 800m to the west, across a prominent, fault-controlled, north-trending creek. Hazelton strata west of this creek comprise red tuffs and shallow marine, fossiliferous tuffaceous sediments of the Smithers formation.

Major north to northwest-trending faults transect the claims and the immediate adjacent strata. The west boundary fault near the claim separates stratigraphically younger Jurassic strata to the west from older strata on the claim area. To the south of the claim, a northwest trending fault separates strata on the claims from still older Hazelton assemblages. The claims are located astride the junction of major fault structures.

Strata on the claims comprise poorly exposed fine-grained maroon tuff, tuffaceous mudstone, fine-grained grey green tuff and

DATE

coarse-grained lapilli tuff. Exposures are generally poor as the tuffs weather to a pervasive mantle of fine red felsenmeer and soil. Bedding, where visible, appears to strike north to northeast, dipping 25 to 50 degrees westerly.

MINERALIZATION AND ALTERATION:

The claims were staked because high silver values in association with electrum have been reported from the Colorado Adit. The property was first discovered in 1909 but no work of any significance has been done on the property since 1915.

The 1987 work, centred on the caved Colorado Adit, consisted of reconnaissance geologic mapping, soil sampling and basic prospecting.

Two, poor exposures of mineralization were noted. A small area of proximal float containing galena and tetrahedrite in a quartz-carbonate rock assayed 49 oz/ton Ag, with low Au. A one meter chip at the adit location gave 4 oz/ton Ag and a grab returned >100 ppm Ag.

ROCK GEOCHEMISTRY:

Rock chip samples collected in the course of mapping were analyzed by ICP techniques for 28 elements and by FA & AAS for gold. Analyses were conducted by Vangochem Labs, Vancouver, and the results are included in Appendix 1. Twenty three samples were analyzed.

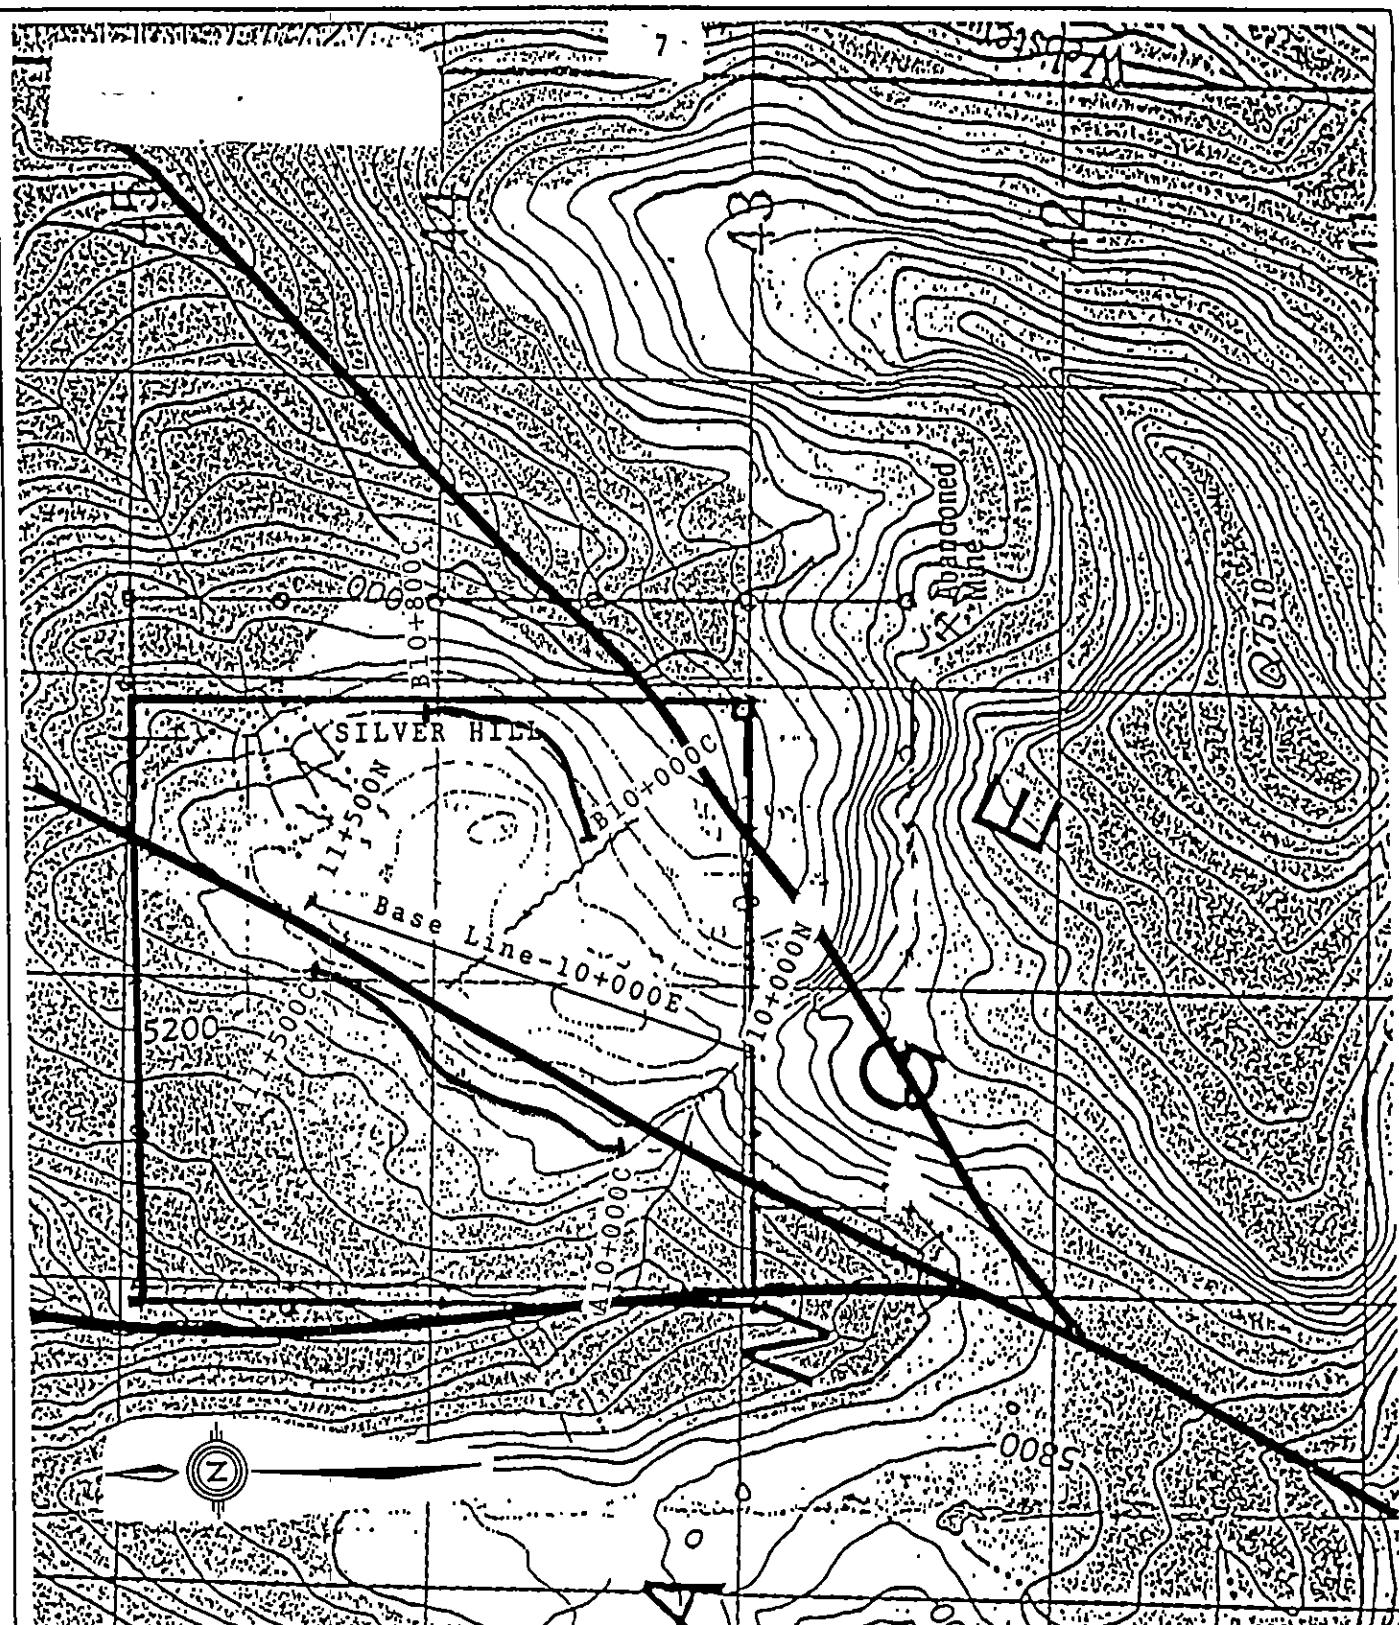

Samples ML 10A, 10B and 11-15 were mineralized. Samples ML 1-9 and 16-22 were character and rock type samples.

The sample locations are plotted on Figure 4, and values in Au and Ag are also plotted on this map. ML 13 ran 165 ppb Au and >100 ppm Ag.

SOIL GEOCHEMISTRY:

A soil survey, on 100m lines with samples 25m apart, was completed over the central part of the property (Figure 3). Soils were taken from a depth of 5-15cm and from the B horizon wherever possible. Soils were placed in kraft paper bags and shipped to the Vancouver laboratory.

Copper in soil, when results are contoured, outlines two distinctive, overlapping trends (see Figure 4). A northerly trend divides the grid area into two panels; to the east, soils

are generally less than 40 ppm and to the west, greater than 40 ppm. This pattern reflects underlying bedrock. Second-order trends define a set of northeast elongate anomalies that are coincident with northeast trending fault structures. The mapped direction of the Colorado Adit (see Figure 5) also follows this trend, and the 49 oz/ton Ag assay-showing also lies on a northeast trending structure. Copper values in excess of 75 ppm and 110 ppm (values range to 817 ppm) outline these anomalies. A soil sample at the adit gave >100 ppm Ag, 7240 ppm Cu, 249 ppm Sb, 214 ppm As and 49 ppb Cd.

Silver in soils includes values to 6.3 ppm, exclusive of the dump sample. Sample sites where silver was greater than 0.8 ppm are also plotted on Figure 4. Gold values are generally low, with values greater than 30 ppm somewhat aligned with copper and silver. Two soil samples taken off the grid gave results of 120 and 500 ppb Au. The anomalous geochemical trends remain open to the north and south.

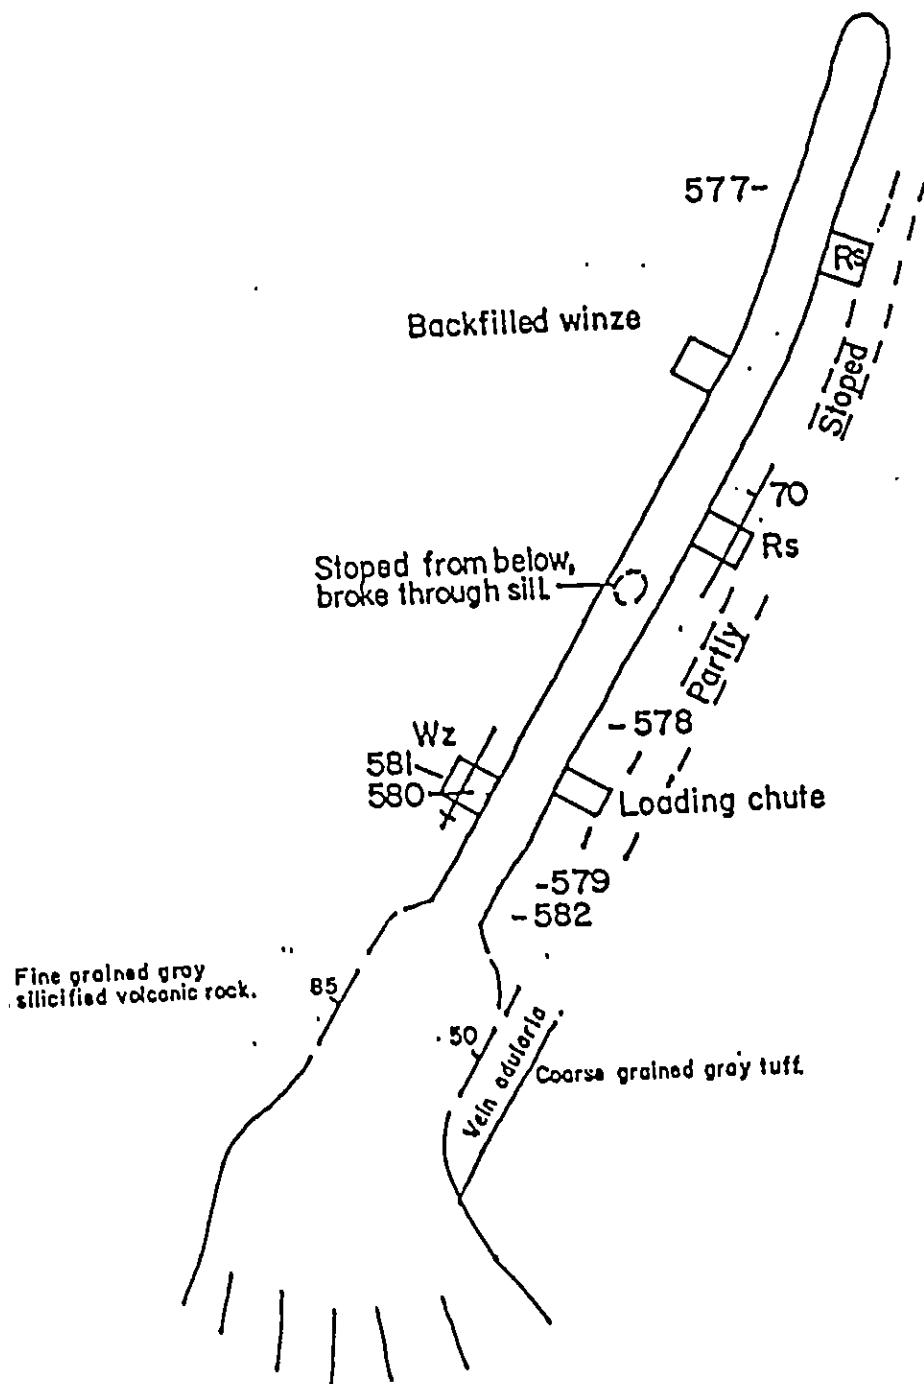

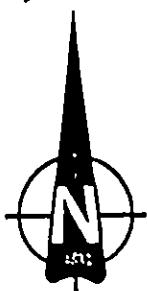

CONCLUSIONS AND RECOMMENDATIONS:

The claim area contains at least four major north-trending structures that are geochemically anomalous in copper and silver and are associated with known exposures or proximal float with high silver values. Electrum has been reported from the claims (B.C. Dept. of Mines Assessment Report #10918). An assay taken in 1912 reports: Cu 18%, Ag 400 oz/ton, and Au 0.12 oz/t.

The soil survey indicates a high correlation between fault structures and Cu and Ag anomalies. Completion of a tighter spaced soil grid is expected to better define this correlation.

In addition, VLF-EM surveys will assist in the definition of the faulting on the property.

At the conclusion of the soil and VLF-EM surveys, soil anomalies clearly coincident with structure should be trenched.

AUTHOR'S STATEMENT

I, Colin Harivel, do hereby state the following;

1. I am a mineral exploration geologist with business address P.O. Box 233, Smithers, B.C. Postal Code V0J 2N0.
2. I graduated from the University of British Columbia in 1972 with a B.Sc. in geology and I have since then practised my profession in Australia, Canada and the United States of America.
3. I am a Fellow of the Geological Association of Canada.
4. I have explored for ore deposits of the type that may be contained in the Silver Hill Property, the subject property in this report.
5. I visited the property on July 5, 1987. This report is based on a literature review and on observations made by me and by associates who were present on that date.

Signed:

COLIN HARIVEL, B.Sc., F.G.A.C.

ICAP GEOCHEMICAL ANALYSIS

A .5 GRAM SAMPLE IS DIGESTED WITH 5 ML OF 3:1:2 HCl TO HNO₃ TO H₂O AT 95 DEG. C FOR 90 MINUTES AND IS DILUTED TO 10 ML WITH WATER.
 THIS LEACH IS PARTIAL FOR Si, K, Fe, Ca, P, Cr, Ni, Ba, Pb, Al, Na, K, H, Pt AND Sr. Au AND PD DETECTION IS 3 PPM.
 IS= INSUFFICIENT SAMPLE, ND= NOT DETECTED, = NOT ANALYZED
