## 1. SUMMARY

The Reef Claim is situated 4 kilometers east of the town of Atlin, in northwestern British Columbia. During the period June through October 1987, as part of a large exploration effort in the Atlin area, Homestake Mineral Development Company Ltd. established 22.5 line-kilometers of cut-line grid on the property, from which geological mapping and lithogeochemical sampling programs were conducted.

The mapping program discovered only two small areas of outcrop exposure, along the shores of Pine and Spruce Creeks. Encountered lithologies included serpentized ultramafic and andesite, with minor occurrences of feldspar porphyry dyke rocks. There is insufficient outcrop exposure to allow interpretation of the property geology, although regional airborne magnetic data suggest that the majority of the ground is underlain by massive homogeneous andesites of the Cache Creek Group.

Five rock samples were collected from the property during mapping, and analyzed geochemically for Au and via ICP for a suite of 30 elements. Only one sample, from andesite containing 10% thin carbonate stringers, returned even weakly anomalous gold values, that being 69 ppb Au.

## 2. INTRODUCTION

### 2.1 Scope of Report

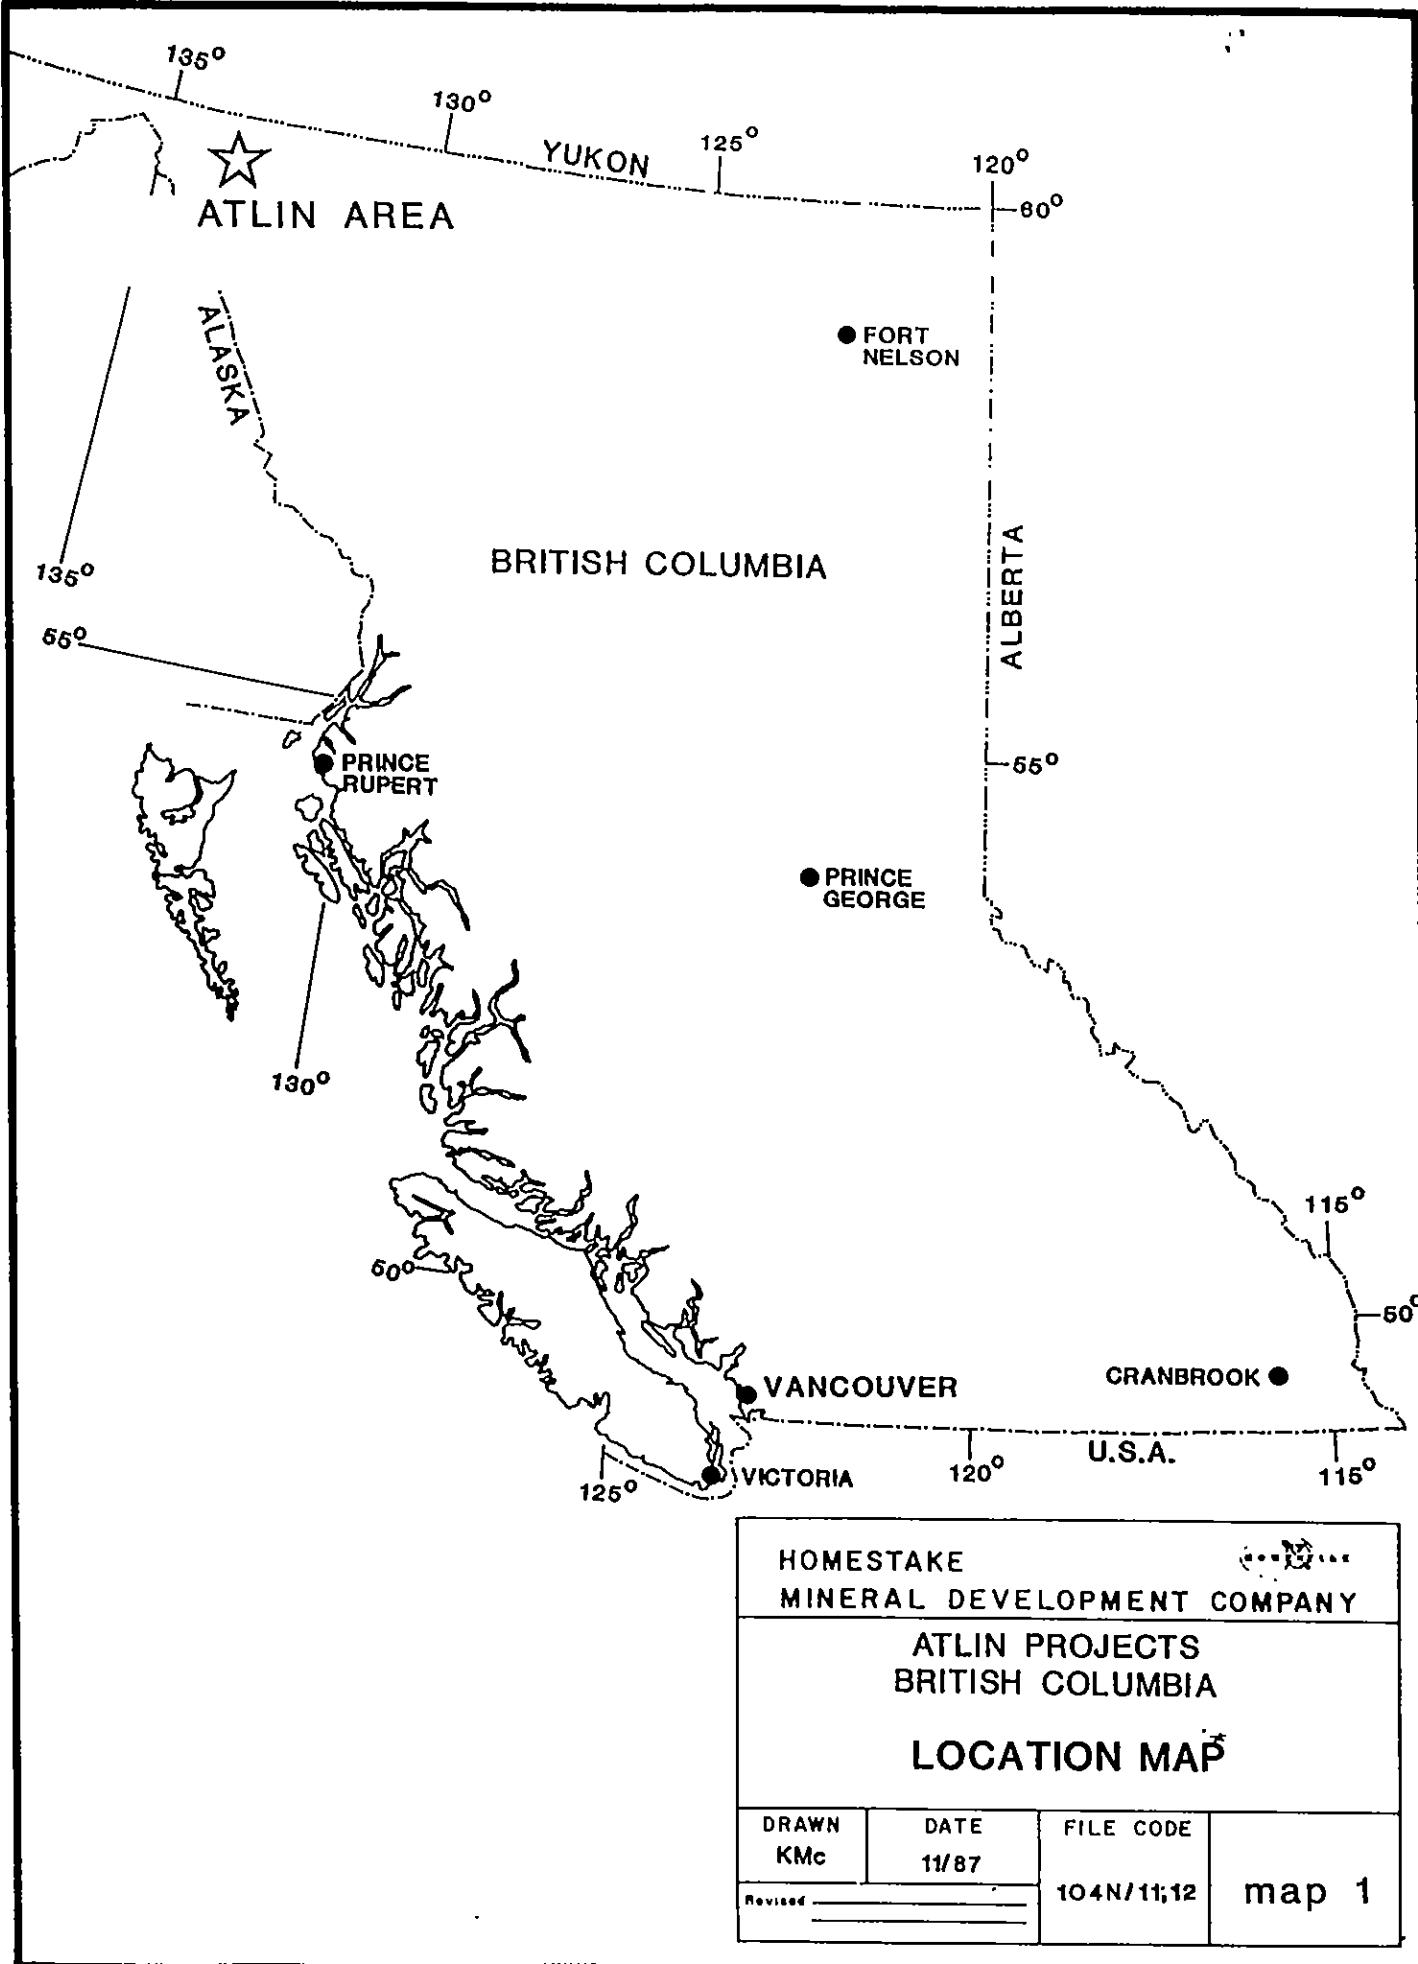

This report briefly summarizes the exploration work conducted by Homestake Mineral Development Company Ltd., on portions of the Reef Claim during the period June through October 1987.

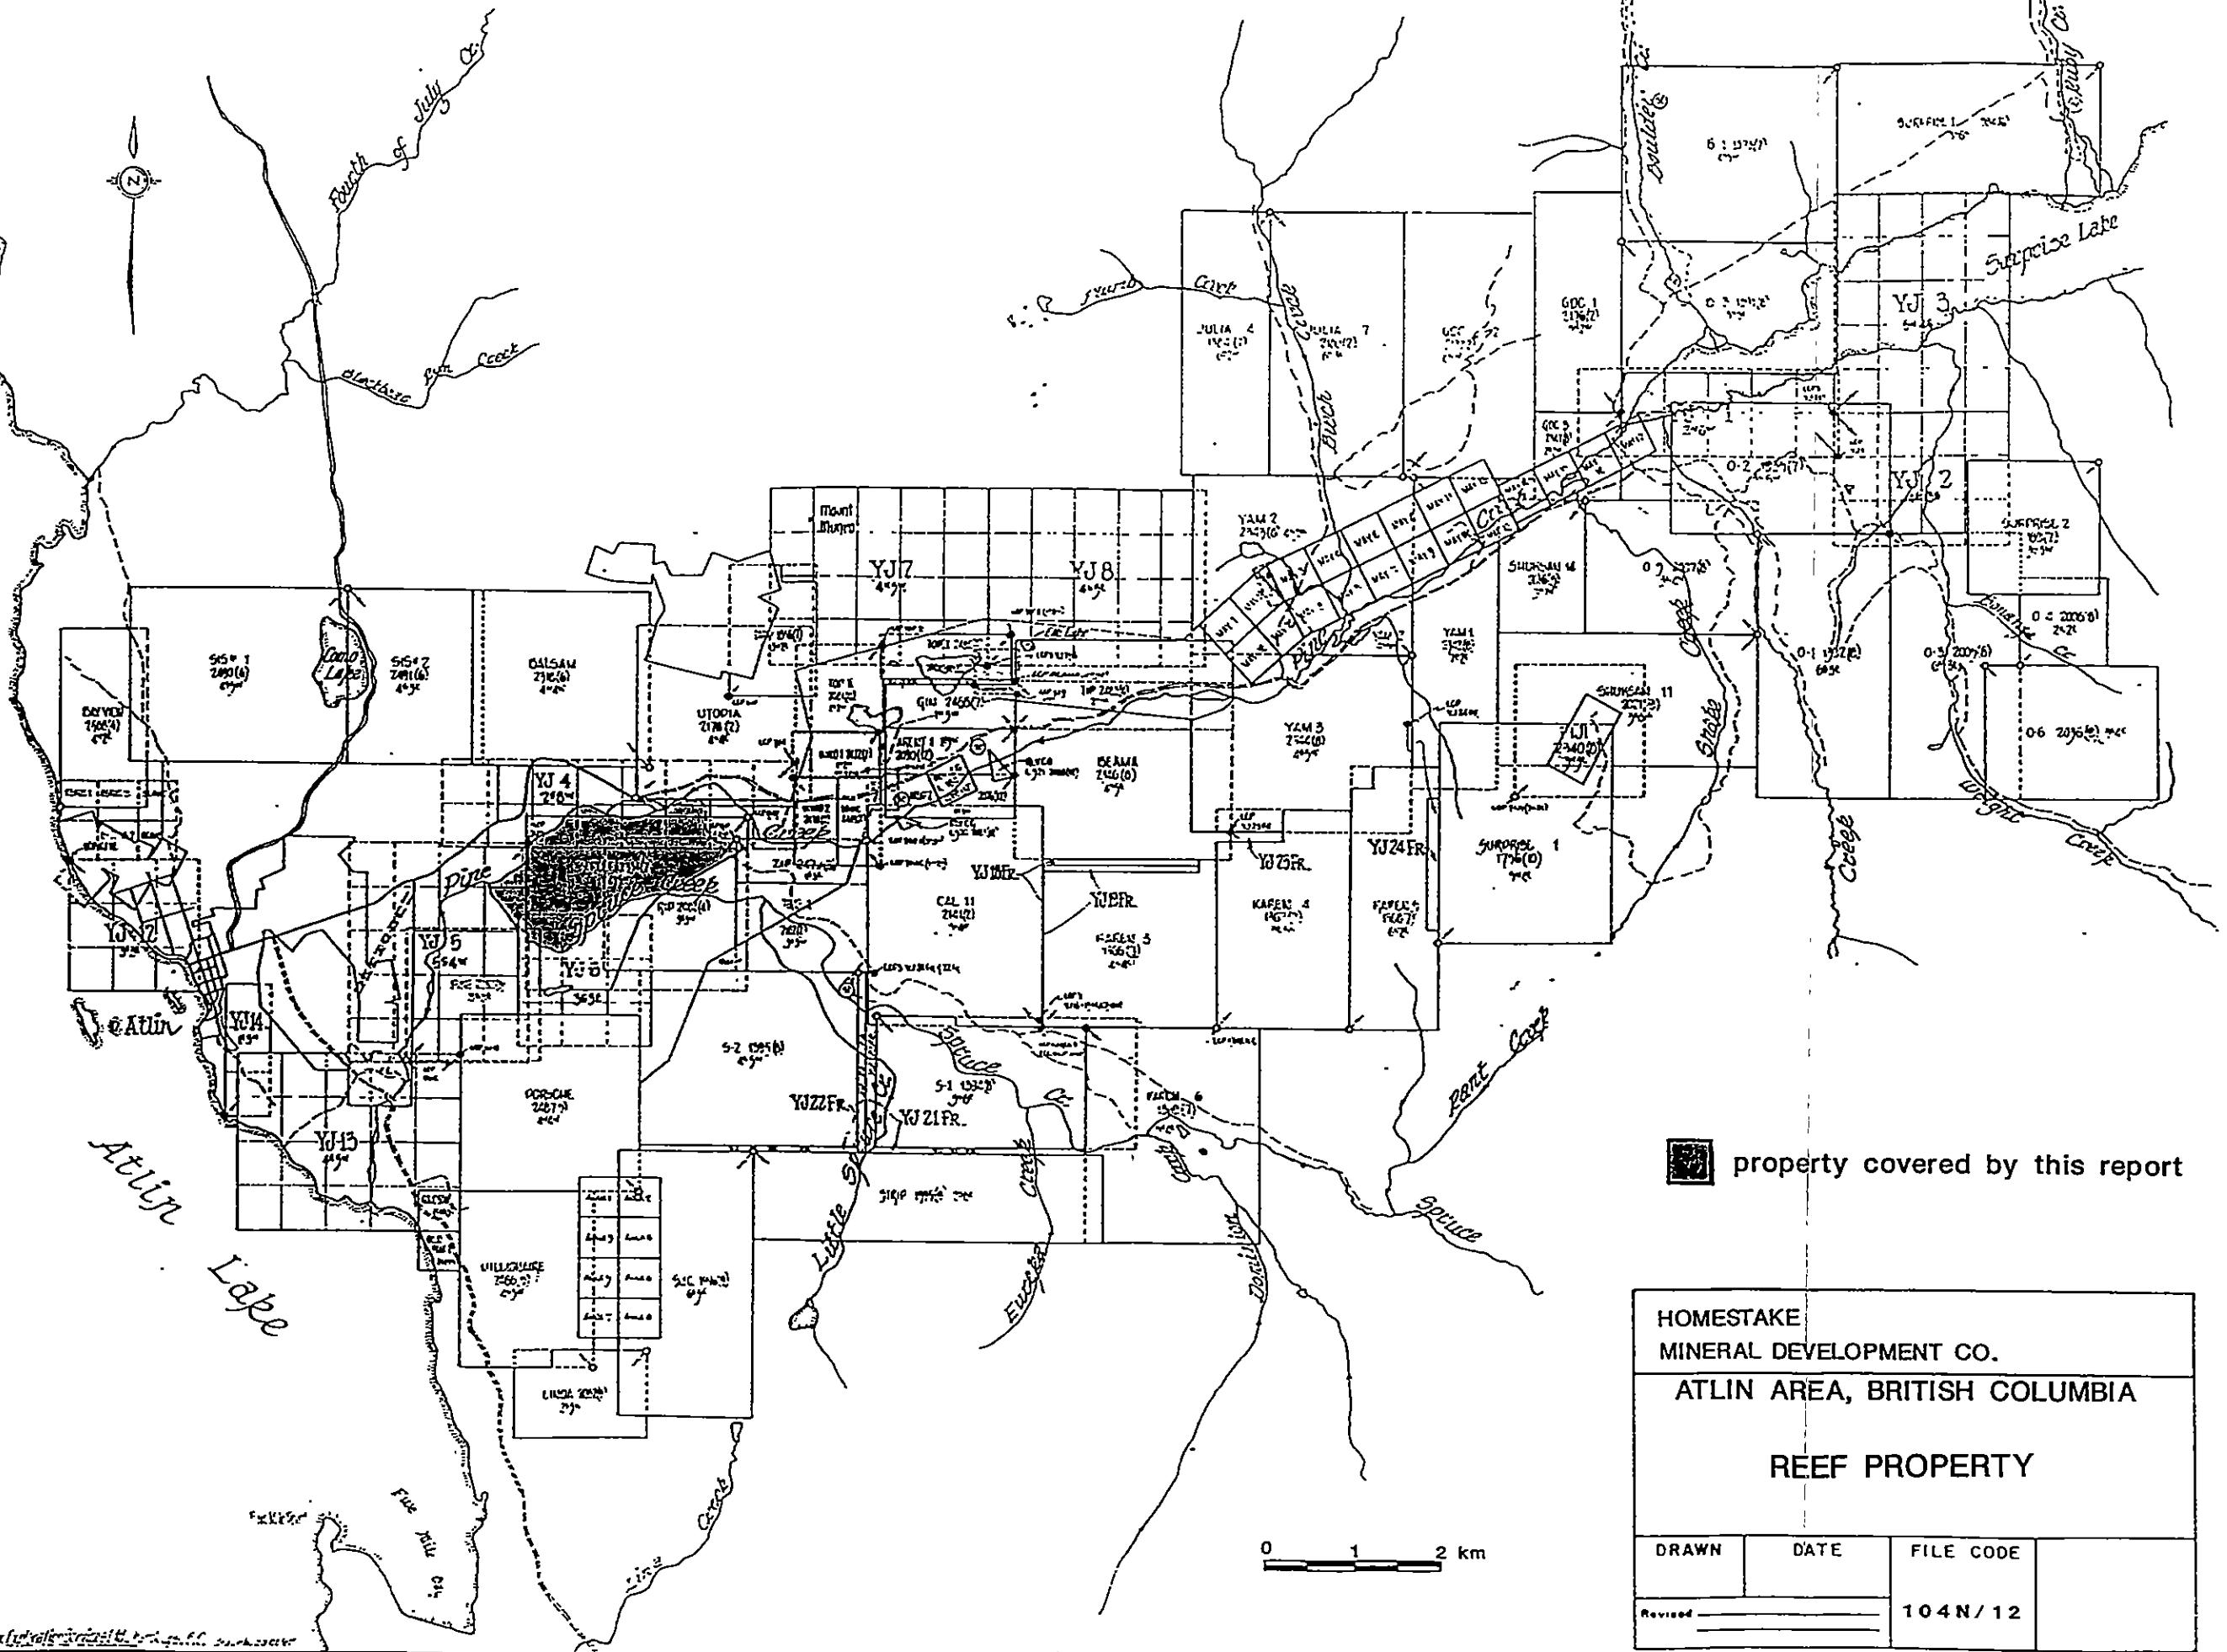

### 2.2 Location, Access and Physiography

The Reef Claim is located 4 kilometers due east of the town of Atlin, in northwestern British Columbia (see Figures 1 and 2). Access to the property is excellent, with several 4WD bush roads extending west from the Spruce Creek Road and crossing the property. The portion of the Reef Claim on which work was performed this year is bounded on the north by Pine Creek, and to the south and west by Spruce Creek. The majority of the claim is overlain by a thick mantle of fluvial and glacial sediments, and outcrop exposure constitutes less than 1% of the property area. The majority of this exposure is along the two aforementioned creeks. The claim is densely wooded, with mature spruce and jackpine the most common vegetation. Relief on the property is by local standards low, with perhaps a maximum of 30 meters difference between the creek valleys and higher plain between the creeks.

### 2.3 Land Status

The 20 unit Reef claim is part of a larger group of claims (collectively known as the West Group), all of which are in good standing until late 1988.

## 2.4 General Geologic Setting

The Reef claim lies near the western edge of the northwest trending "Atlin Terrane", which is underlain by Upper Paleozoic oceanic crustal rocks (Monger, 1975). These rocks are correlated with the Cache Creek Group rocks of southern and central British Columbia.

Within the Atlin Terrane, andesitic to basaltic flows are overlain by cherts and thick shallow water carbonate rocks. Discordant granitic plutons, ranging in age from Late Jurassic to early Tertiary, locally intrude the stratigraphy. Some remnant Tertiary volcanics and sediments are found within the area.

Also within the Atlin Terrane, and co-eval or immediately post dating the Cache Creek group rocks, are large ultramafic bodies which define a discordant belt trending west across the tectonic fabric of the terrane. The ultramafic bodies are commonly intensely serpentinized, and in places extensively hydrothermally altered to a listwanite-like assemblage of silica-carbonate-mariposite/fuchsite.

The Reef claim is believed to be underlain predominantly by rocks of the Cache Creek Group (andesitic to basaltic flows, with minor intercalated meta-sediments), with some intrusive ultramafic rocks in the extreme north and south portions of the property. Figure 3, illustrates the general geology of the Atlin area, and the location of the Reef Claim within that geologic setting.

## 2.5 Preliminary Economic Assessment

The majority of known lode gold mineralization within the Atlin Camp is associated with intensely altered (silica-carbonate-mariposite/fuchsite) ultramafic rocks proximal to their fault bounded or intrusive contacts with rocks of the Cache Creek Group.

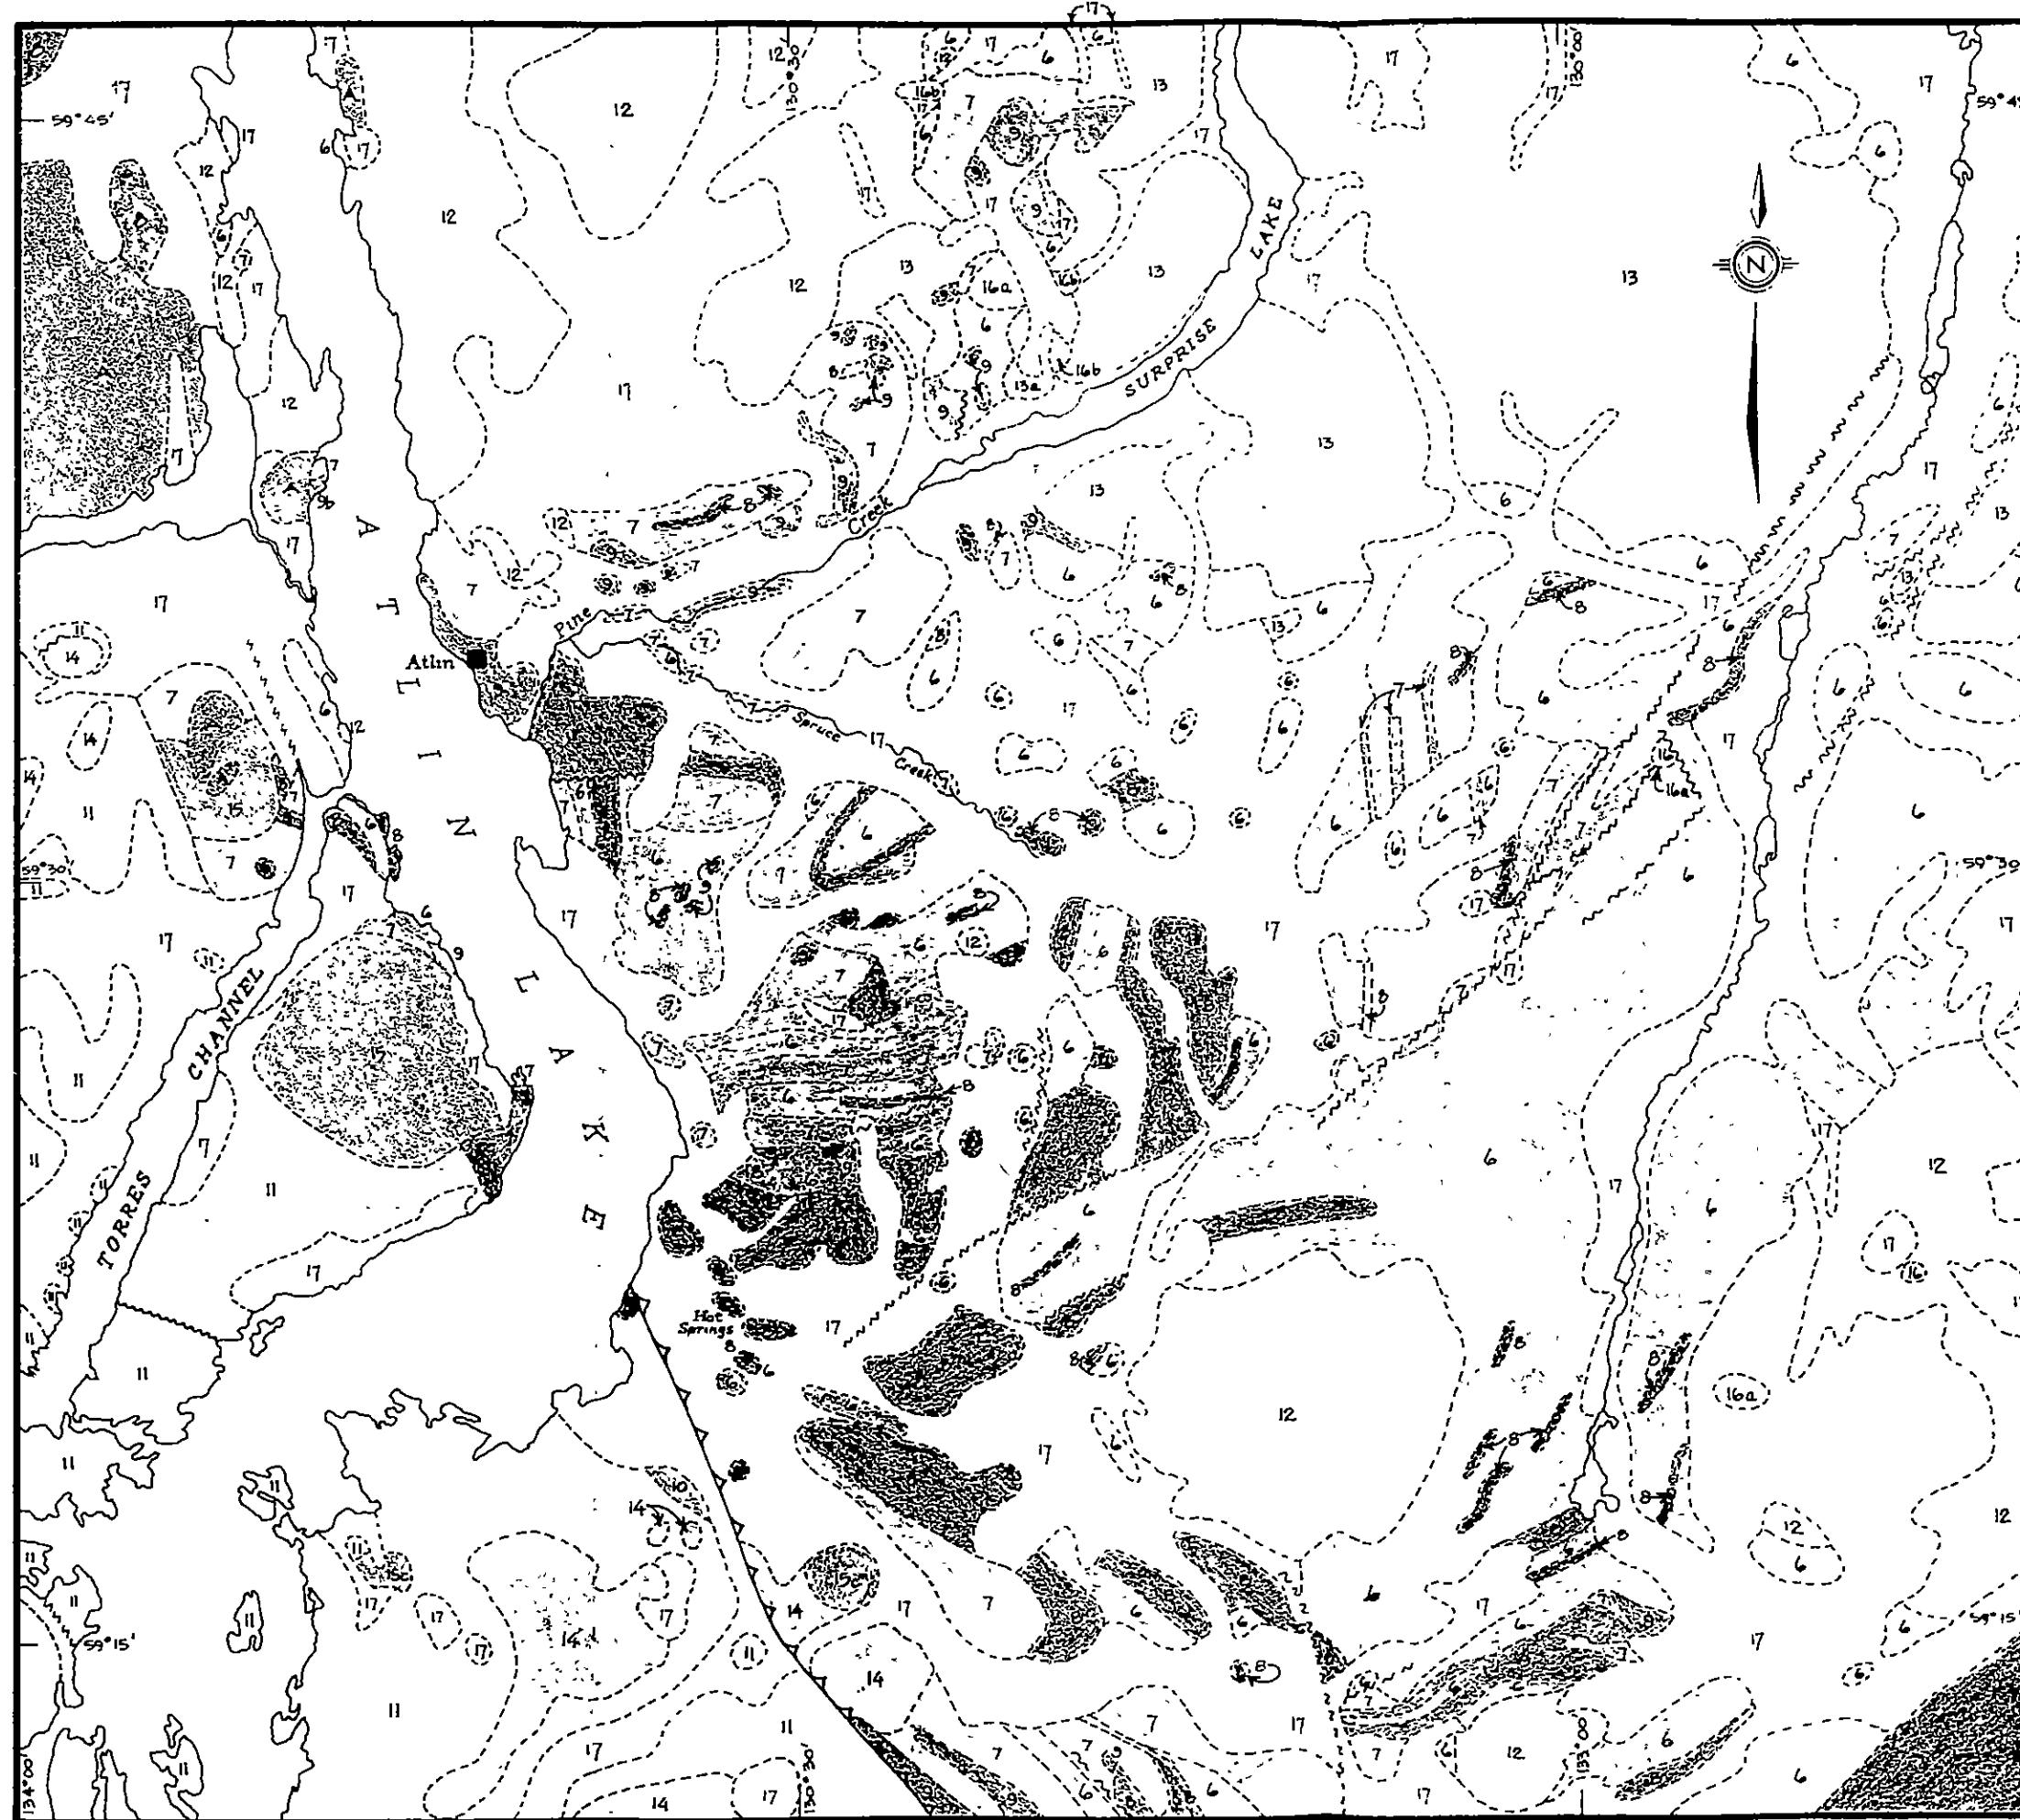

The mineralization is almost exclusively hosted in quartz-quartz-carbonate veins and vein stockworks within these altered packages of rocks, occurring either as often spectacular free gold, or in intimate association with gangue sulphides such as pyrite, chalcopyrite, arsenopyrite, sphalerite, galena, and sulfosalts (pyrargyrite, tetrahederite).

The Reef claim, in as much as it is believed to be underlain by contacts between ultramafic rock in the north, and Cache Creek rocks through the central portion of the property, may host areas of hydrothermally altered ultramafics along these contacts, which may in turn host potentially auriferous quartz/quartz-carbonate vein stockworks.

The Reef Claim lies 5 kilometers west and along strike from Homestake's Yellowjacket zone of gold mineralization, which is hosted in a geological environment similar to that discussed above.

## 2.6 Exploration History

Prior to acquisition by Homestake Mineral Development Company Ltd., no recorded work has been filed on the claim.

## 2.7 Work Completed to Date

During the period June through October 1987, the following work was completed by Homestake (HMDC) on the property;

- 22.5 kilometers of grid were cut on the property, to facilitate geological mapping.
- geological mapping, at a scale of 1:2000 was completed on the property.
- 5 samples were collected from the property and analyzed for 30 elements via ICP, and for Au via standard fire assay and A.A. methods.

The details of this work are outlined in the next section of this report.

## 3. DETAILED TECHNICAL DATA

### 3.1 Geological Mapping

#### 3.1.1. Methods Employed

As mentioned, 22.5 line-kilometers were cut on the property, to provide control for geological mapping and any potential future work. The grid was an extension of the Yellowjacket grid bordering the property to the east, and involving extending a baseline 2 kilometers across the southern portion of the claim. Baseline orientation was 070°/250°, from which crosslines at 340°/160° were established at 100 meter intervals. Stations were established at 20 meter intervals along each cross-line.

In the course of mapping, all encountered outcrops were physically tied into the grid, and their perimeters followed via hip-chain and compass. The provided very accurate establishment of outcrop locations.

Detailed notations as to outcrop lithology, structural orientation, and the presence or absence of any significant alteration, veining, and mineralization were made in the field.

All pertinent topographic and geomorphic features were also accurately tied into the grid.

The geology map of the property, at a scale of 1:2000, appears in Appendix 1 of this report.

### 3.1.2. Results

#### Lithologies

Outcrop exposure on the property constituted less than 1%, occurring only sporadically along Pine Creek in the north and Spruce Creek in the South. Four lithologies were encountered during mapping, and below are brief descriptions, their numbers corresponding with those of the map legend in Appendix 1.

#### Unit 2 - Serpentinized Ultramafic

This unit occurs as a very fine grained to aphanitic, predominantly massive bright green to black, strongly serpentinized rock, the serpentine content varying from approximately 30% to 100%. The rock weathers a characteristic tan to buff colour, and is generally very strongly magnetic. The unit is in places porphyritic, with small 2-3mm weakly steatized pyroxene crystals which stand out in relief on weathered surfaces.

Where weakly sheared (see map), talc alteration increases at the expense of serpentine.

#### Unit 5 - Feldspar Porphyry

This lithology outcrops as thin dykes cutting andesites in the northeast corner of the property. The rock is comprised of an intermediate, massive, very fine grained to aphanitic groundmass with a highly variable phenocryst content, from nil to 20%. Phenocrysts are predominantly euhedral to subhedral white plagioclase.

#### Unit 9 - Andesite

This unit, which outcrops along both Spruce and Pine Creeks, is believed to underlie the majority of the property. It is characteristically massive, dark green, aphanitic, and uniformly unspectacular.

#### Unit 12 - Argillite/Graywacke/Quartzite

In the northeast corner of the property, a thin wedge of fine grained pink granular quartzitic appearing rock cuts a serpentinized ultramafic outcrop. This may either be a broken and rafted "xenolith" of quartzite, or a recrystallized felsic dyke.

#### Structural/Stratigraphic Setting

The poor exposure on the property makes interpretation of the structural and stratigraphic relationship of the property geology difficult, but based on what outcrop is present, and the regional magnetic data, it would appear that;

- the majority of the property is underlain by a thick pile of intermediate (andesitic) volcanics of the Cache Creek Group. Regional orientation of these volcanics, based on aeromagnetic data and observed orientations elsewhere in the Atlin area, is predominantly east-west, with vertical to sub-vertical dips.

This volcanic package has been locally intruded by ultramafic rocks to an unknown extent, as there is insufficient ground exposure or detailed magnetometer coverage to allow delineation of these units.

### 3.2 Lithogeochemical Sampling

#### 3.2.1. Methods Employed

In the course of mapping, 5 bedrock samples were collected from the property, and forwarded to Acme Analytical Laboratories in Vancouver for 30 element geochemical ICP analysis. All samples were also geochemically analyzed for gold by standard fire assay and atomic absorption methods.

Obviously, the purpose of the sampling program was to evaluate the economic potential of the property, and all exposures containing any form of alteration, mineralization or veining were sampled. In addition to the gold analyses, the wide spectrum of elements analyzed for by the ICP method provides some very useful trace element geochemical data. Gold mineralization in the Atlin camp is often associated with highly elevated contents of Cu, Zn, Pb, Sb, As, Cd and Ag, all of which are part of the ICP package. Elevated contents of these elements, even in the absence of gold anomalies, may serve as pathfinders to gold mineralization.

The ICP geochemical analytical results appear in Appendix 2 of this report. All sample locations are plotted on the enclosed geology map (Appendix 1), followed by the sample gold content in ppb.

#### 3.2.2. Results

Of the five samples collected during mapping, only one returned even weakly anomalous gold values, that being;

##### Sample EZ-33226

A grab sample of andesite in the northeast corner of the property, which locally contained 5-10% thin carbonate stringers with 1% disseminated pyrite, returned an assay of 69 ppb Au and 0.5 ppm Ag. This area of exposure warrants a more vigorous sampling program to assess the significance of the weakly anomalous gold value.

All other samples returned insignificant Au and associated trace element values.

#### 4.0 ITEMIZED COST STATEMENT AND ALLOCATION OF EXPENDITURES

##### 4.1 Itemized Cost Statement

The following expenses were incurred as a direct result of the exploration work described in this report.

1) Linecutting Costs  
22.0 kilometers @ \$375.00 per kilometer,  
(as invoiced by Eaglehead Exploration) \$8,250.00

2) Salaries and Wages

Duncan McIvor: (Report Preparation)  
1 day (December 6, 1987)  
@\$115.00/day \$ 115.00

Joanne Bozek:  
5 days (August 3-6, 11, 1987)  
@\$85.00/day \$ 425.00

Phil Southam:  
4 days (August 3-6, 1987)  
@\$85.00/day \$ 340.00

SUB TOTAL \$ 880.00

+20% BENEFITS, ETC. 176.00

TOTAL \$1,056.00

3) Analytical Costs

5 samples, analyzed for Au & 30 additional elements, @\$14.25/sample \$ 71.25

4) Food and Accommodation Costs

@\$35/day per man x 9 man days \$ 315.00

5) Transportation Costs

Fuel and Maintenance on Vehicles  
@\$25/day x 5 days \$ 125.00

6) Miscellaneous Field Equipment Costs

- flagging tape, topofil, sample bags, etc. \$ 50.00

TOTAL EXPENDITURES \$9,867.25

#### 4.2 Allocation of Expenditures

These costs were all incurred and are all allocated to the Reef Claim (2334), part of the "West Group" of claims. Application of these expenditures to claims of the West Group is as outlined on the Statement of Exploration and Development.
