LOCATION MAP

VOLCANO & JASE CLAIMS

NEW BRIDGE

DEVELOPMENT CORPORATION

DATE 14-04-88

SCALE

1:8,000,000

1) SUMMARY AND CONCLUSIONS

The Volcano and Jase claims are located 7 Km north east from the operating silver, lead zinc mine of Teck Corporation at Beaverdell, B.C.

Limited exploration on the claims over the last 10 to 20 years has disclosed indications of lead, zinc, silver mineralization associated with quartz rich shear zones in limestone and altered metavolcanics near intrusive contacts.

Intrusive activity has resulted in a pervasive pyritization of the older metavolcanics, volcanics and sediments.

Positive results from the 1987 geochemical survey indicate a sizeable area in the SE corner of the claims that warrants further investigation for lead, zinc, silver and gold.

2) INTRODUCTION

This report has been prepared at the request of J.P. Stevenson and Associates Ltd. for New Bridge Development Corporation.

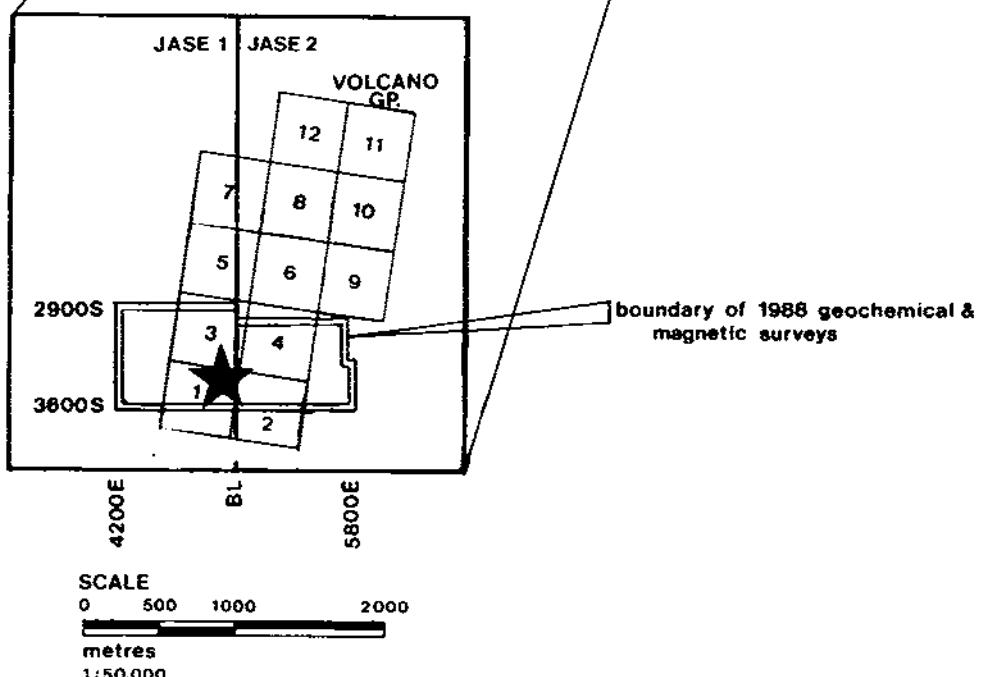

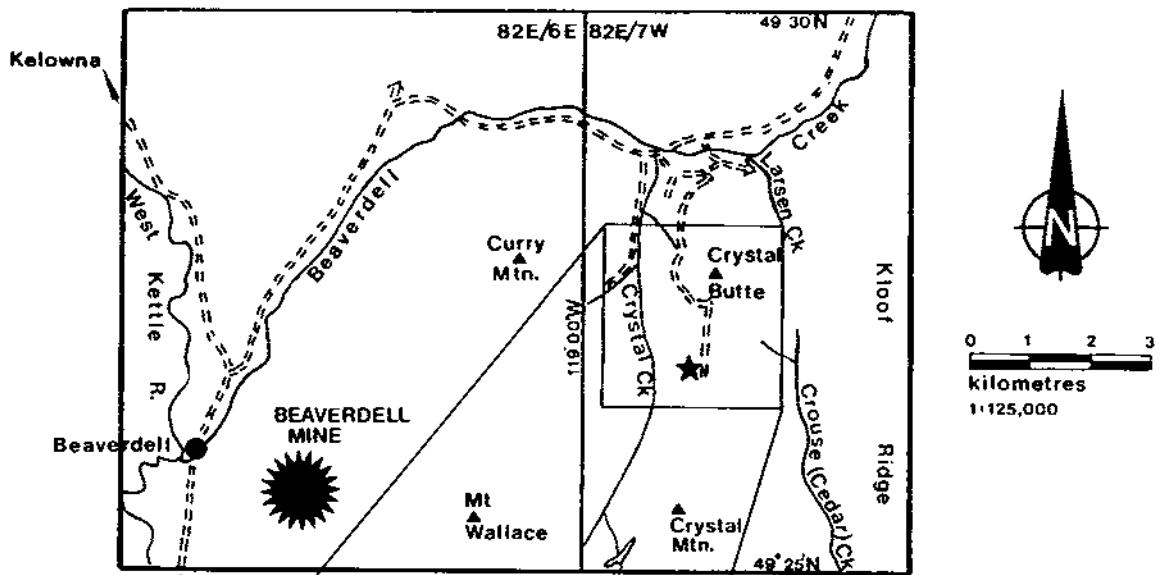

The writer examined the claims on May 1 and 8, 1988, and collected two samples for assay. The results of the survey completed as early as January, 1988, which included a magnetometer survey and soil sampling, were evaluated by J.P. Stevenson and his staff.

3) LOCATION, ACCESS AND PHYSIOGRAPHY

The subject property is located 100 Kms south of Kelowna, B.C. and 50 Kms north of the United States border. The approximate geographic centre of the claims is Lat. 49 degrees, 27 minutes; Long. 118 degrees, 58 minutes.

Access is by 10 Kms of all weather gravel road north east from the town of Beaverdell and then 4 Kms of old logging road to the centre of the claims.

Elevations range from 3500' (1067 m) at the NW corner of the claims to 4900' (1493 m) near the centre of the block. The terrain is moderate to steep and the area has been partially logged in the last 20 years.

4) CLAIMS

The property consists of the following claims:

<u>Claim</u>	<u># Units</u>	<u>Record #</u>	<u>Expiry Date</u>
Volcano 1	1	4652	August, 1993
Volcano 2	1	4653	August, 1993
Volcano 3	1	4654	August, 1993
Volcano 4	1	4655	August, 1993
Volcano 5	1	4656	August, 1993
Volcano 6	1	4657	August, 1993
Volcano 7	1	4658	August, 1993
Volcano 8	1	4659	August, 1993
Volcano 9	1	4722	September, 1993
Volcano 10	1	4723	September, 1993
Volcano 11	1	4724	September, 1993
Volcano 12	1	4725	September, 1993
Jase 1	18	5091	January, 1994
Jase 2	18	5092	January, 1994

New Bridge Development Corporation has an option to purchase the claims from the recorded: G. Houlind, Box 84, Beaverdell, B.C. & R. Hart, Site 5, Comp 53, R.R. #3, Kamloops, B.C.

5) HISTORY

The claims lie 7 Kms at N 60 degrees E from the operating silver, lead zinc mine of Teck Corporation at Beaverdell.

Earliest recorded work in the district began with claim locations at the Beaverdell mine in 1896-1897. Production at the mainly "silver" mine began in 1900 and has continued to date.

Mineralization at Teck's Beaverdell Mine has an approximate N 60E degree trend. The subject claims are "on strike" with known mineralization although no connection is evident. Remains of a very old cabin are located near an area of old trenches which would indicate prospecting and some follow up work took place more than 50 years ago.

6) REGIONAL GEOLOGY AND MINERALIZATION

The Beaverdell district has been mapped in detail by Reinecke in 1915 and published in GSC Memoir 79. GSC map 538A "Kettle River West Half" describes the geology more completely.

The district is underlain primarily by the West Kettle batholith of Jurassic age. This large intrusive body contains screens and roof pendants of the Permian Wallace Formation and has been intruded by the early Tertiary Beaverdell stock.

The Wallace Formation, now correlated with part of the Anarchist Group to the south, consists of metamorphosed andesitic tuffs and lavas, basic intrusions, hornfels, quartzite and minor limestone.

The West Kettle batholith ranges in composition from granodiorite to quartz diorite. It is generally a medium grained, massive rock containing both biotite and hornblende. Mafic minerals are usually highly chloritized in the vicinity of mineralized areas.

The Beaverdell stock occupies an area of about 1.5 square miles centred about the village of Beaverdell. It is highly chloritized, unfoliated, porphyritic quartz monzonite. It is characterized by large, pink orthoclase phenocrysts up to 8 centimetres in length. This stock has been dated at approximately 50 Ma, the same age as the bulk of the mineralization at Beaverdell, and is considered to be genetically related to it.

the veins which constitute the ore zones on the Teck ground are mineralized fissures which trend easterly in the western part of the camp and change direction to north-easterly as the contact with the Wallace Formation is approached. Dips are steep to moderate to the south or southeast. Mineralization locally extends into the Wallace Formation but these veins rapidly narrow and pinch out.

Most of the veins are consistent in appearance and mineralogy. The main metallic minerals are galena, sphalerite and pyrite in a gangue of quartz and lesser calcite. Other metallic minerals encountered are arsenopyrite, tetrahedrite, pyrargyrite, chalcopyrite, pyrrhotite, polybasite, acanthite and native silver.

Wall rock alteration in the form of chlorite, sericite and epidote is common as an envelope around the large veins. In places it may extend outward from each vein wall for as much as 20 feet. This green, generally chloritic alteration is referred to as "ore ground" and is an important prospecting aid at the mine.

7) PROPERTY GEOLOGY AND MINERALIZATION

Geological mapping of the Volcano and Jase claims (previously staked as the HK claims) was completed in 1981 by G. Allan, P. Eng., and filed as assessment report #10470. This mapping shows that the claims are underlain by similar lithologies to the Beaverdell area 7 Km to the SW.

The central area shows a large granodiorite mass of the Nelson intrusion intruding the older "Wallace" formation which is composed of quartzitic metavolcanics, metasediments and limestone.

Intruding all rocks are a series of north/south trending andesite, porphyritic andesite, trachyandesite and monzo-diorite dykes showing varying degrees of chloritic and pyritic alteration.

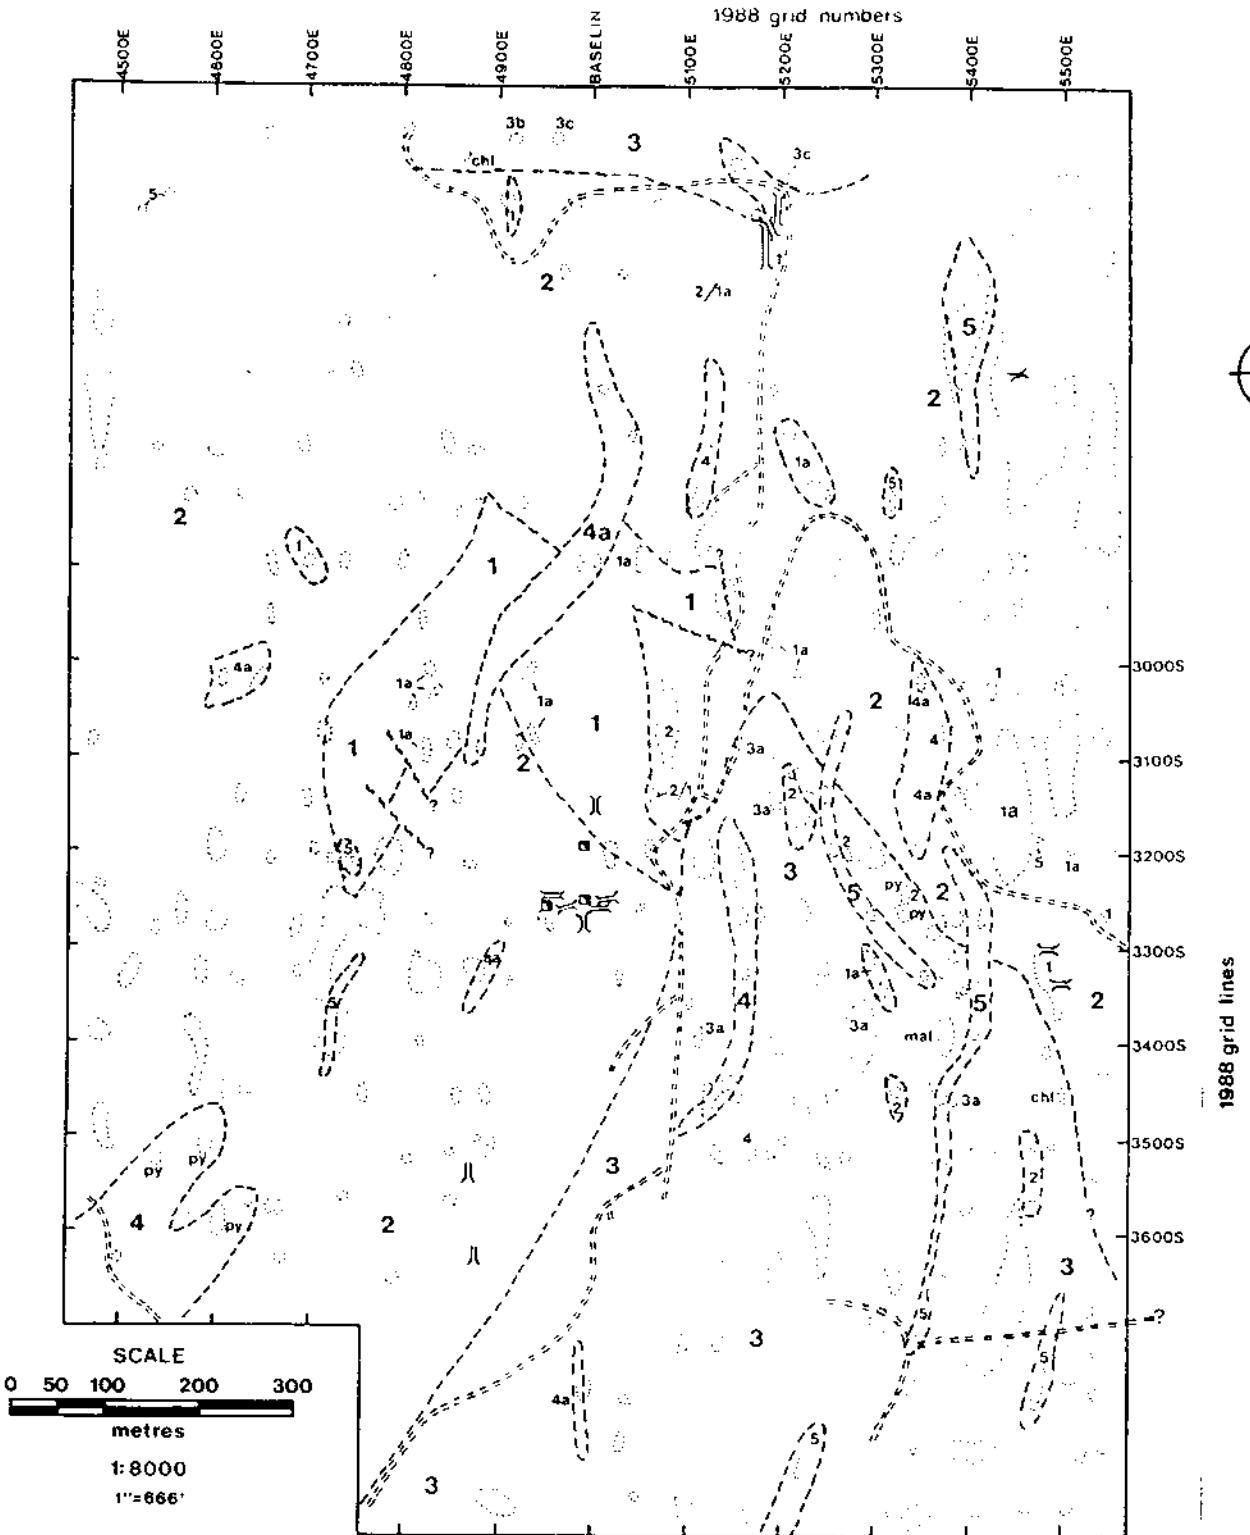

Large gossanous are are present on the claims, and the whole claim group has the appearance of having undergone some degree of alteration and mineralization.

Pyrite is widespread in the Wallace formation and is a minor constituent in many of the mapped dykes.

Several trenches, adits and small shafts are located at approximately 5000E and 3250W, 4850E and 3550W, 4880E and 3650W, 5500E and 3350S, and 5200E and 2500W. The first three were put in on a number of quartz veins associated with shear zones. These quartz veins have a general north south orientation with steep dips to both east and west. They are irregularly mineralized with galena, sphalerite and traces of chalcopyrite. Assays by J. McClintock, P.Eng. (1988) yielded the following values:

<u>Sampler</u>	<u>Width</u>	<u>Pb %</u>	<u>Zn %</u>	<u>Ag oz/ton</u>	<u>Au oz/ton</u>
McClintock	46 cm	.32	1.05	0.20	0.10
McClintock	grab	7.10	-	2.70	-

Areas of the property underlain by limy units of the Wallace formation have undergone various degrees of alteration and mineralization, especially in the vicinity of intrusive dykes. A heavy limonite coating on the limestone is apparent and many areas show silicification and heavy pyritization. Allan noted galena, sphalerite and chalcopyrite in "shear zones in calc-silicate quartzose rock." Assays to date from limestone areas have generally been less than those reported above.

AMENDED BY ALEX FRASER Bsc

FIGURE 3	NTS 82E/7W
DATE 3-05-88	af

8) GEOCHEMICAL AND GROUND MAGNETIC SURVEYS

A 14 line Km soil geochemical and ground magnetic survey over the south central area of the claims was completed during 1988. The results of the above survey are presented as Figure 4.

a) Geochemistry

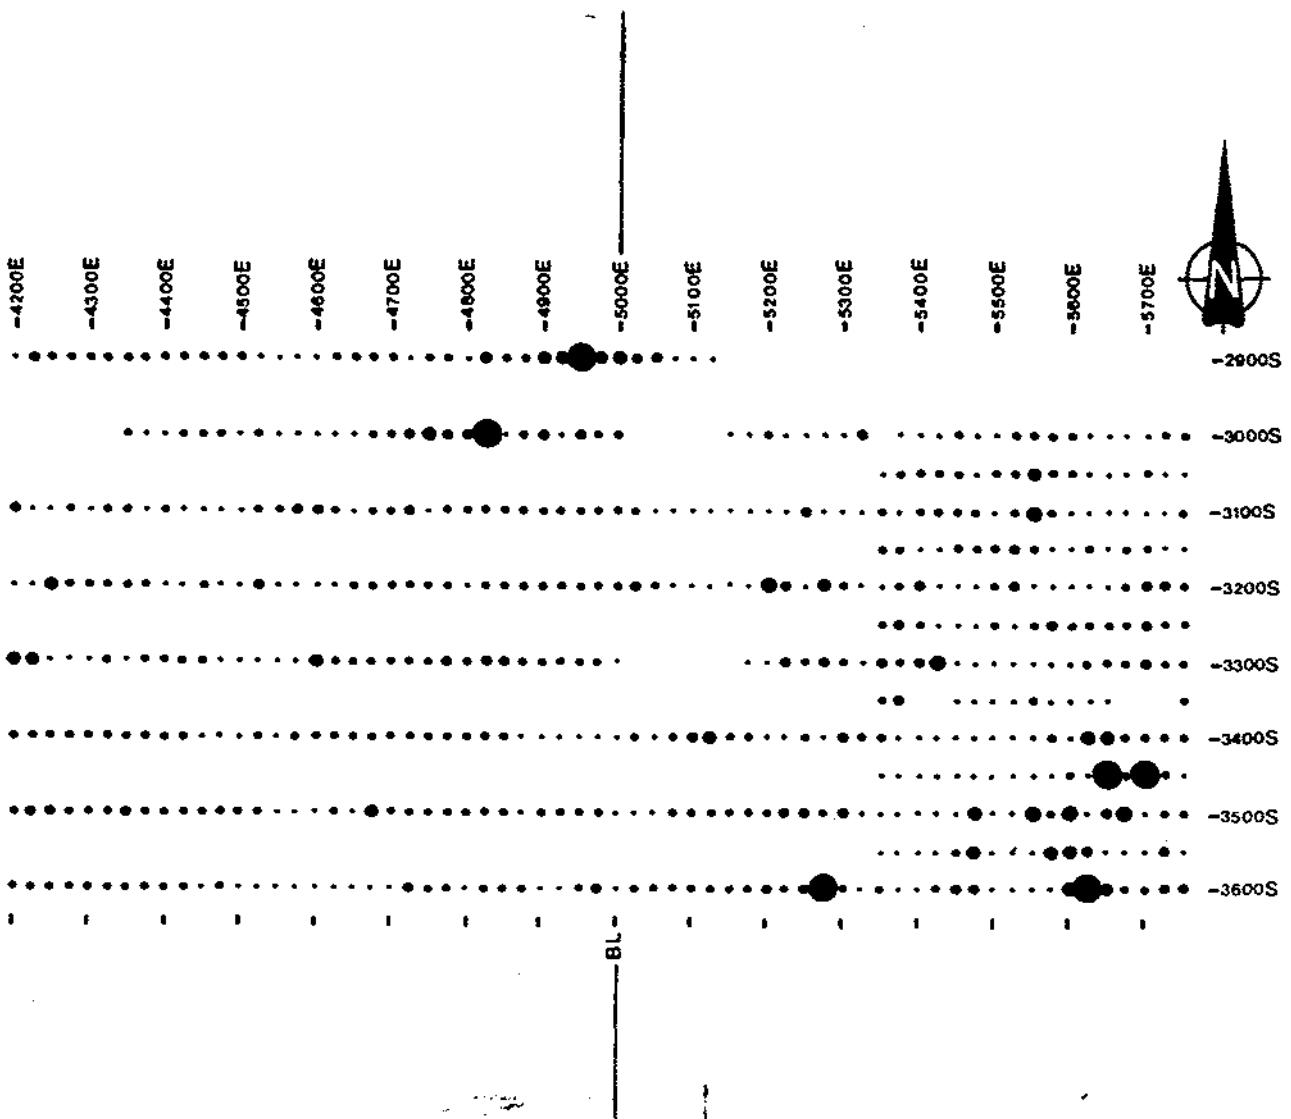

Geochemical analyses were conducted on 264 soil samples collected in December 1987. At each station, a sample of "B" horizon soil was collected at a 20 - 30 cm depth and placed into a numbered kraft paper envelope. The soil samples were forwarded to Acme laboratories in Vancouver. Each sample was analyzed for 29 elements plus gold by standard ICP analytical techniques.

The analytical results from the samples were statistically analyzed using frequency distribution histograms to determine the mean and anomalous level for each element analyzed.

The following elements are listed and their data plots included following this page due to their regional economic significance.

<u>Element</u>	<u>Mean</u>	<u>S.D.</u>	<u>Threshold Mean +1 S.D.</u>	<u>Anomalous Mean +2 S.D.</u>	<u>Highest Value</u>
Cu ppm	30	21	51	72	141
Pb ppm	23	30	53	83	340
Zn ppm	254	555	809	1364	1752
Ag ppm	0.4	0.3	0.7	1.0	3.2
Au ppb	3	6	9	15	64
As ppm	13	12	25	37	149

The most noteworthy results are for lead, zinc, arsenic and gold. Lead and zinc are anomalous in a grouping in the SE corner of the grid over an area of 600 meters by 300 meters with a general NW/SE orientation. Gold and arsenic occur to the north and flanking the lead/zinc anomaly. The lack of a correlating silver anomaly is not unexpected, for even if it were present, silver has very poor dispersion characteristics in this area. It is interesting to note, however, the highest silver value of 3.2 ppm occurs near the centre of the lead/zinc anomaly.

FIGURE 12 NTS 82E/7W

DATE 21-05-88

af

A ground traverse by the writer through the area of the lead/zinc anomaly indicated the intense intrusive dyke activity. This area plus its extension to the SE warrants further work. A piece of float, in the middle of the anomalous area, consisting of quartz and heavy pyrite, assayed 1.19 oz/ton Ag and 0.01 oz/ton Au.

One additional sample was taken near the high zinc value located at 3000S, 5200E. This area is underlain by limestone intruded by a porphyritic andesite dyke. The limestone is poorly exposed but shows intense limonite alteration. Assay results returned only background values for Au and Ag.

A general overview of the geochemical data indicates no strong anomalous conditions existing in the areas of the known showings other than spot highs. This observation enhances the grouping of lead/zinc/gold/silver values in the SE 1/4 of the gridded area.

b) Ground Magnetics

A ground magnetic survey completed in 1987 does not disclose any noteworthy "large" anomalies. Data is presented in Figure 4. Spot highs occur in the central north area of the gridded area at 4800-5000E and 2900-3000S. These values may be associated with skarn development in the limestone units adjacent to intrusive dykes.

An increase in magnetic strength in the SE corner of the grid has a rough correlation with the geochemical anomalies and is of interest.

9) RECOMMENDATIONS AND COST ESTIMATE

A two phase continuing exploration program is recommended to test for economic concentrations of silver, lead and zinc which are known to occur in the area in similar geological environments to that of the Volcano/Jase claims.

Phase II would be contingent on successful completion with encouraging results from Phase I.

PHASE I

1. Geological mapping, sampling and supervision – detail mapping in the SE $\frac{1}{4}$ of existing grid, extend and map grid to SE to the claim boundary. Reconnaissance mapping should be completed over the remainder of the claims.

2. Detailed fill in geochemical sampling, ground magnetic and EM-16 surveys on the SE $\frac{1}{2}$ of the existing grid with fill in lines @ 50 m intervals. Extend the surveys to the SE to the claim boundary.

30 mandays @ \$150/manday 4,500.00

3. Trenching on existing geochemical anomalies and improve road/trail access to the SE area of the claim block.
D6 cat equivalent.

GEOCHEMICAL ANALYSIS CERTIFICATE

ICP - .500 GRAM SAMPLE IS DIGESTED WITH JML 3-1-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR AND IS DILUTED TO 10 ML WITH WATER.
 THIS LEACH IS PARTIAL FOR Mn Fe Ca P La Cr Mg Ba Ti B W AND LIMITED FOR Na K AND Al. Au DETECTION LIMIT BY ICP IS 3 PPM.
 - SAMPLE TYPE: SOIL Au ANALYSIS BY AA FROM 10 GRAM SAMPLE.
